3.8V-36V Vin, 6A, High Efficiency Synchronous Step-down DCDC Converter with Programmable Frequency

FEATURES
- Wide Input Range: 3.8V-36V
- Up to 6A Continuous Output Current
- 0.8V ±1% Feedback Reference Voltage
- Integrated 36mΩ High-Side and 13mΩ Low-Side Power MOSFETs
- Pulse Skipping Mode (PSM) with 25uA Quiescent Current in Sleep Mode
- 100ns Minimum On-time
- Adjustable Soft-start Time
- Adjustable Frequency 100KHz to 2.2MHz
- External Clock Synchronization
- Frequency Spread Spectrum (FSS) Modulation for EMI Reduction
- Precision Enable Threshold for Programmable Input Voltage Under-Voltage Lock Out Protection (UVLO) Threshold and Hysteresis
- Low Dropout Mode Operation
- Over-voltage and Over-Temperature Protection
- Available in 3mmx4mm QFN-10L Package

APPLICATIONS
- Battery Pack Powered System - Cordless Power Tools, Cordless Home Appliance, Drone, Aero Modeling, GPS Tracker etc.
- Cigarette Lighter Adapters, Chargers
- USB Type-C Power Delivery, USB Charging
- Industrial and Medical Distributed Power Supplies
- Optical Communication and Networking System
- Automotive System

DESCRIPTION
The SCT2460 is 6A synchronous buck converters with wide input voltage, ranging from 3.8V to 36V, which integrates a 36mΩ high-side MOSFET and a 13mΩ low-side MOSFET. The SCT2460, adopting the peak current mode control, supports the Pulse Skipping Modulation (PSM) with typical 25uA low quiescent current which assists the converter on achieving high efficiency at light load or standby condition.

The SCT2460 features programmable switching frequency from 100 kHz to 2.2 MHz with an external resistor, which provides the flexibility to optimize either efficiency or external component size. The converter supports external clock synchronization with a frequency band from 100kHz to 2.2MHz. The SCT2460 allows power conversion from high input voltage to low output voltage with a minimum 100ns on-time of high-side MOSFET.

The SCT2460 is an Electromagnetic Interference (EMI) friendly buck converter with implementing optimized design for EMI reduction. The SCT2460 features Frequency Spread Spectrum FSS with ±6% jittering span of the 500kHz switching frequency and modulation rate 1/512 of switching frequency to reduce the conducted EMI.

The SCT2460 offers cycle-by-cycle current limit and hiccup over current protection, thermal shutdown protection, output over-voltage protection and input voltage under-voltage protection. The device is available in 3mmx4mm QFN-10L package.

(1) Stresses beyond those listed under Absolute Maximum Rating may cause device permanent damage. The device is not guaranteed to function outside of its Recommended Operation Conditions.

(2) The max VIN transient voltage is guaranteed by design and verified on bench.

(3) The IC includes over temperature protection to protect the device during overload conditions. Junction temperature will exceed 150°C when over temperature protection is active. Continuous operation above the specified maximum operating junction temperature will reduce lifetime.

RT/CLK  |  6  | Set the internal oscillator clock frequency or synchronize to an external clock. Connect a resistor from this pin to ground to set switching frequency. An external clock can be input directly to the RT/CLK pin. The internal oscillator synchronizes to the external clock frequency with PLL. If detected clocking edges stops, the operation mode automatically returns to resistor programmed frequency.

SS   |  7  | Connect a cap to ground, program the soft start time.

EN   |  8  | Enable pin to the regulator with internal pull-up current source. Pull below 1.1V to disable the converter. Float or connect to VIN to enable the converter. The tap of resistor divider from VIN to GND connecting EN pin can adjust the input voltage lockout threshold.

VIN  |  9  | Input supply voltage. Connect a local bypass capacitor from VIN pin to GND pin. Path from VIN pin to high frequency bypass capacitor and GND must be as short as possible.

SW   | 10  | Regulator switching output. Connect SW to an external power inductor.

(1) SCT provides R<sub>BJA</sub> and R<sub>BJC</sub> numbers only as reference to estimate junction temperatures of the devices. R<sub>BJA</sub> and R<sub>BJC</sub> are not a characteristic of package itself, but of many other system level characteristics such as the design and layout of the printed circuit board (PCB) on which the SCT2460 is mounted, thermal pad size, and external environmental factors. The PCB board is a heat sink that is soldered to the leads and thermal pad of the SCT2460. Changing the design or configuration of the PCB board changes the efficiency of the heat sink and therefore the actual R<sub>BJA</sub> and R<sub>BJC</sub>.

OPERATION

Overview

The SCT2460 is a 3.8V-36V input, 6A output, EMI friendly synchronous buck converter with built-in 36mΩ Rdson high-side and 13mΩ Rdson low-side power MOSFETs. It implements constant frequency peak current mode control to regulate output voltage, providing excellent line and load transient response and simplifying the external frequency compensation design.

The switching frequency is programmable from 100KHz to 2.2MHz with two setting modes, resistor setting frequency mode and the clock synchronization mode, to optimizes either the power efficiency or the external components’ sizes. The SCT2460 features adjustable soft-start time to avoid large inrush current and output voltage overshoot during startup. The device also supports monolithic startup with pre-biased output condition. The seamless mode-transition between PWM mode and PSM mode operations ensure high efficiency over wide load current range. The quiescent current is typically 25uA under no load or sleep mode condition to achieve high efficiency at light load.

The SCT2460 has a default input start-up voltage of 3.5V with 400mV hysteresis. The EN pin is a high-voltage pin with a precision threshold that can be used to adjust the input voltage lockout thresholds with two external resistors to meet accurate higher UVLO system requirements. Floating EN pin enables the device with the internal pull-up current to the pin. Connecting EN pin to VIN directly starts up the device automatically.

The SCT2460 implements the Frequency Spread Spectrum FSS modulation spreading of ±6% centered selected switching frequency. FSS improves EMI performance by not allowing emitted energy to stay in any one receiver band for a significant length of time.

The SCT2460 full protection features include the input under-voltage lockout, the output over-voltage protection, over current protection with cycle-by-cycle current limiting and hiccup mode, output hard short protection and thermal shutdown protection.

Peak Current Mode Control

The SCT2460 employs fixed frequency peak current mode control. An internal clock initiates turning on the integrated high-side power MOSFET Q1 in each cycle, then inductor current rises linearly. When the current through high-side MOSFET reaches the threshold level set by the COMP voltage of the internal error amplifier, the high-side MOSFET turns off. The synchronous low-side MOSFET Q2 turns on till the next clock cycle begins or the inductor current falls to zero.

The error amplifier serves the COMP node by comparing the voltage of the FB pin with an internal 0.8V reference voltage. When the load current increases, a reduction in the feedback voltage relative to the reference raises COMP voltage till the average inductor current matches the increased load current. This feedback loop well regulates the output voltage to the reference. The device also integrates an internal slope compensation circuitry to prevent sub-harmonic oscillation when duty cycle is greater than 50% for a fixed frequency peak current mode control.

The SCT2460 operates in Pulse Skipping Mode (PSM) with light load current to improve efficiency. When the load current decreases, an increment in the feedback voltage leads COMP voltage drop. When COMP falls to a low clamp threshold (400mV typically), device enters PSM. The output voltage decays due to output capacitor discharging during skipping period. Once FB voltage drops lower than the reference voltage, and the COMP voltage rises above low clamp threshold. Then high-side power MOSFET turns on in next clock pulse. After several switching cycles with typical 1A peak inductor current, COMP voltage drops and is clamped again and pulse skipping mode repeats if the output continues light loaded.

This control scheme helps achieving higher efficiency by skipping cycles to reduce switching power loss and gate drive charging loss. The controller consumption quiescent current is 25uA during skipping period with no switching to improve efficiency further.

Enable and Under Voltage Lockout Threshold

The SCT2460 is enabled when the VIN pin voltage rises about 3.5V and the EN pin voltage exceeds the enable threshold of 1.18V. The device is disabled when the VIN pin voltage falls below 3.1V or when the EN pin voltage is
below 1.1V. An internal 1.5uA pull up current source to EN pin allows the device enable when EN pin floats.

EN pin is a high voltage pin that can be connected to VIN directly to start up the device.

For a higher system UVLO threshold, connect an external resistor divider (R1 and R2) shown in Figure 9 from VIN to EN. The UVLO rising and falling threshold can be calculated by Equation 1 and Equation 2 respectively.

\[
V_{\text{rise}} = 1.18 \times \left(1 + \frac{R_1}{R_2}\right) - 1.5\mu A \times R_1 \quad (1)
\]

\[
V_{\text{fall}} = 1.1 \times \left(1 + \frac{R_1}{R_2}\right) - 5.5\mu A \times R_1 \quad (2)
\]

where

- \(V_{\text{rise}}\) is rising threshold of Vin UVLO
- \(V_{\text{fall}}\) is falling threshold of Vin UVLO

**Output Voltage**

The SCT2460 regulates the internal reference voltage at 0.8V with ±1% tolerance over the operating temperature and voltage range. The output voltage is set by a resistor divider from the output node to the FB pin. It is recommended to use 1% tolerance or better resistors. Use Equation 3 to calculate resistance of resistor dividers. To improve efficiency at light loads, larger value resistors are recommended. However, if the values are too high, the regulator will be more susceptible to noise affecting output voltage accuracy.

\[
R_{FB,\text{TOP}} = \left(\frac{V_{\text{OUT}}}{V_{\text{REF}}} - 1\right) \times R_{FB,\text{BOT}} \quad (3)
\]

where

- \(R_{FB,\text{TOP}}\) is the resistor connecting the output to the FB pin.
- \(R_{FB,\text{BOT}}\) is the resistor connecting the FB pin to the ground.

**Programmable Soft-Start**

The SCT2460 features programmable soft-start time to prevent inrush current during start-up stage. The soft-start time can be programmed easily by connecting a soft-start capacitor \(C_{ss}\) (\(C_{ss}\) is the C13 on Figure 9) from SS pin to ground.

The SS pin sources an internal 3μA current charging the external soft-start capacitor \(C_{ss}\) when the EN pin exceeds turn-on threshold. The device adopts the lower voltage between the internal voltage reference 0.8V and the SS pin voltage as the reference input voltage of the error amplifier and regulates the output. The soft-start completes when the voltage at the SS pin exceeds the internal reference voltage of 0.8V.

The soft-start capacitor value can be calculated going with following equation 4. Attention should be taken here that the programmed soft-start time should be larger than 4ms.

\[
C_{\text{soft-start}} = t_{ss} \times \frac{3\mu A}{0.8V} \quad (4)
\]

Where:

- \(C_{ss}\) is the soft-start capacitor connected from SS pin to the ground
- \(t_{ss}\) is the soft-start time

**Switching Frequency and Clock Synchronization**

The switching frequency of the SCT2460 is set by placing a resistor between RT/CLK pin and the ground, or synchronizing to an external clock.
In resistor setting frequency mode, a resistor placed between RT/CLK pin to the ground sets the switching frequency over a wide range from 100KHz to 2.2MHz. The RT/CLK pin voltage is typical 0.5V. RT/CLK pin is not allowed to be left floating or shorted to the ground. Use Equation 5 or the plot in Figure 10 to determine the resistance for a switching frequency needed.

\[
RT(K\Omega) = \frac{100000}{f_{sw}(KHz)}
\]  

(5)

where,

\(f_{sw}\) is switching clock frequency

In clock synchronization mode, the switching frequency synchronizes to an external clock applied to RT/CLK pin. The synchronization frequency range is from 100KHz to 2.2MHz and the rising edge of the SW synchronizes to the falling edge of the external clock at RT/CLK pin with typical 66ns time delay. A square wave clock signal to RT/CLK pin must have high level no lower than 2V, low level no higher than 0.4V, and pulse width larger than 80ns.

In applications where both resistor setting frequency mode and clock synchronization mode are needed, the device can be configured as shown in Figure 16. Before an external clock is present, the device works in resistor setting frequency mode. When an external clock presents, the device automatically transitions from resistor setting mode to external clock synchronization mode. An internal phase locked loop PLL locks internal clock frequency onto the external clock within typical 85us. The converter transitions from the clock synchronization mode to the resistor setting frequency mode when the external clock disappears.

**Frequency Spread Spectrum**

To reduce EMI, the SCT2460 implements Frequency Spread Spectrum (FSS). The FSS circuitry shifts the switching frequency of the regulator periodically within a certain frequency range around the programmed switching frequency. The jittering span is ±6% of the switching frequency with 1/512 swing frequency. This frequency dithering function is effective for both frequency programmed by resistor placed at RT/CLK pin and an external clock synchronization application.

**Bootstrap Voltage Regulator and Low Drop-out Operation**

An external bootstrap capacitor between BOOT pin and SW pin powers the floating gate driver to high-side power MOSFET. The bootstrap capacitor voltage is charged from an integrated voltage regulator when high-side power MOSFET is off and low-side power MOSFET is on.

The UVLO of high-side MOSFET gate driver has rising threshold of 2.7V and hysteresis of 350mV. When the device operates with high duty cycle or extremely light load, bootstrap capacitor may be not recharged in considerable long time. The voltage at bootstrap capacitor is insufficient to drive high-side MOSFET fully on. When the voltage across bootstrap capacitor drops below 2.35V, BOOt UVLO occurs. The converter forces turning on low-side MOSFET periodically to refresh the voltage of bootstrap capacitor to guarantee the converter’s operation over a wide duty range.

During the condition of ultra-low voltage difference from the input to the output, SCT2460 operates in Low Drop-Out LDO mode. High-side MOSFET remains turning on as long as the BOOT pin to SW pin voltage is higher than BOOT UVLO threshold 2.7V. When the voltage from BOOT to SW drops below 2.4V, the high-side MOSFET turns off and low-side MOSFET turns on to recharge bootstrap capacitor periodically in the following several switching cycles. Low-side MOSFET only turns on for 100ns in each refresh cycle to minimize the output voltage ripple. Low-side MOSFET may turn on for several times till the bootstrap voltage is charged to higher than 2.7V for high-side MOSFET working normally. The effective duty cycle of the converter during LDO operation can be approaching to 100%

During slowing power up and power down application, the output voltage can closely track the input voltage ramping down thanks to LDO operation mode. As the input voltage is reduced to near the output voltage, i.e. during slowing power-up and power-down application, the off-time of the high side MOSFET starts to approach the minimum value.
Without LDO operation mode, beyond this point the switching may become erratic and/or the output voltage will fall out of regulation. To avoid this problem, the SCT2460 LDO mode automatically reduces the switching frequency to increase the effective duty cycle and maintain regulation.

![Figure 11. LDO Operation Characteristic (Vout = 5V)](image)

**Over Current Limit and Hiccup Mode**

The inductor current is monitored during high-side MOSFET Q1 and low-side MOSFET Q2 on. The SCT2460 implements over current protection with cycle-by-cycle limiting high-side MOSFET peak current and low-side MOSFET valley current to avoid inductor current running away during unexpected overload or output hard short condition.

When overload or hard short happens, the converter cannot provide output current to satisfy loading requirement. The inductor current is clamped at over current limitation. Thus, the output voltage drops below regulated voltage with FB voltage less than internal reference voltage continuously. The COMP pin voltage ramps up to high clamp voltage 3.7V typical. When COMP voltage is clamped for 512 cycles, the converter stops switching. After remaining OFF for 8192 cycles, the device restarts from soft starting phase. If overload or hard short condition still exists during soft-start and make COMP voltage clamped at high for 512 cycles, the device enters into turning-off mode again. When overload or hard short condition is removed, the device automatically recovers to enters normal regulating operation.

The hiccup protection mode above makes the average short circuit current to alleviate thermal issues and protect the regulator.

**Over voltage Protection**

The SCT2460 implements the Over-voltage Protection OVP circuitry to minimize output voltage overshoot during load transient, recovering from output fault condition or light load transient. The overvoltage comparator in OVP circuit compares the FB pin voltage to the internal reference voltage. When FB voltage exceeds 110% of internal 0.8V reference voltage, the high-side MOSFET turns off to avoid output voltage continue to increase. When the FB pin voltage falls below 105% of the 0.8V reference voltage, the high-side MOSFET can turn on again.

**Thermal Shutdown**

The SCT2460 protects the device from the damage during excessive heat and power dissipation conditions. Once the junction temperature exceeds 170°C, the internal thermal sensor stops power MOSFETs switching. When the junction temperature falls below 145°C, the device restarts with internal soft start phase.
Typical Application

Output Voltage

The output voltage is set by an external resistor divider R5 and R6 in typical application schematic. Recommended R6 resistance is 10.2KΩ. Use equation 6 to calculate R5.

\[ R_5 = \left( \frac{V_{OUT}}{V_{REF}} - 1 \right) \times R_6 \]  

(6)

where:
- \( V_{REF} \) is the feedback reference voltage, typical 0.8V

Switching Frequency

Higher switching frequencies support smaller profiles of output inductors and output capacitors, resulting in lower voltage and current ripples. However, the higher switching frequency causes extra switching loss, which downgrads converter’s overall power efficiency and thermal performance. The 100ns minimum on-time limitation also restricts the selection of higher switching frequency. In this design, a moderate switching frequency of 500 KHz is selected to achieve both small solution size and high efficiency operation.

The resistor connected from RT/CLK to GND sets switching frequency of the converter. The resistor value required for a desired frequency can be calculated using equation 6, or determined from Figure 7.

\[ R_3 (K\Omega) = \frac{100000}{fsw (KHz)} \]  

(7)

where:
- \( f_{SW} \) is the desired switching frequency

Under Voltage Lock-Out

An external voltage divider network of R1 from the input to EN pin and R2 from EN pin to the ground can set the input voltage’s Under Voltage Lock-Out (UVLO) threshold. The UVLO has two thresholds, one for power up when the input voltage is rising and the other for power down or brown outs when the input voltage is falling. For the example design, the supply should turn on and start switching once the input voltage increases above 5.7V (start or enable). After the regulator starts switching, it should continue to do so until the input voltage falls below 4.64V (stop or disable). Use Equation 8 and Equation 9 to calculate the values 173 kΩ and 42 kΩ of R1 and R2 resistors.

\[ V_{rise} = 1.18 \times \left( 1 + \frac{R_1}{R_2} \right) - 1.5uA \times R_1 \]  

(8)

\[ V_{fall} = 1.1 \times \left( 1 + \frac{R_1}{R_2} \right) - 5.5uA \times R_1 \]  

(9)

Inductor Selection

There are several factors should be considered in selecting inductor such as inductance, saturation current, the RMS current and DC resistance(DCR). Larger inductance results in less inductor current ripple and therefore leads to lower output voltage ripple. However, the larger value inductor always corresponds to a bigger physical size,
higher series resistance, and lower saturation current. A good rule for determining the inductance to use is to allow the inductor peak-to-peak ripple current to be approximately 20%~40% of the maximum output current.

The peak-to-peak ripple current in the inductor $I_{LPP}$ can be calculated as in Equation 10.

$$I_{LPP} = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times L \times f_{SW}}$$  \hspace{1cm} (10)

Where

- $I_{LPP}$ is the inductor peak-to-peak current
- $L$ is the inductance of inductor
- $f_{SW}$ is the switching frequency
- $V_{OUT}$ is the output voltage
- $V_{IN}$ is the input voltage

Since the inductor-current ripple increases with the input voltage, so the maximum input voltage in application is always used to calculate the minimum inductance required. Use Equation 11 to calculate the inductance value.

$$L_{MIN} = \frac{V_{OUT}}{f_{SW} \times LIR \times I_{OUT(max)} \times (1 - \frac{V_{OUT}}{V_{IN(max)}})}$$  \hspace{1cm} (11)

Where

- $L_{MIN}$ is the minimum inductance required
- $f_{SW}$ is the switching frequency
- $V_{OUT}$ is the output voltage
- $V_{IN(max)}$ is the maximum input voltage
- $I_{OUT(max)}$ is the maximum DC load current
- $LIR$ is coefficient of $I_{LPP}$ to $I_{OUT}$

The total current flowing through the inductor is the inductor ripple current plus the output current. When selecting an inductor, choose its rated current especially the saturation current larger than its peak operation current and RMS current also not be exceeded. Therefore, the peak switching current of inductor, $I_{LPEAK}$ and $I_{LRMS}$ can be calculated as in equation 12 and equation 13.

$$I_{LPEAK} = I_{OUT} + \frac{I_{LPP}}{2}$$  \hspace{1cm} (12)

$$I_{LRMS} = \sqrt{(I_{OUT})^2 + \frac{1}{12} \times (I_{LPP})^2}$$  \hspace{1cm} (13)

Where

- $I_{LPEAK}$ is the inductor peak current
- $I_{OUT}$ is the DC load current
- $I_{LPP}$ is the inductor peak-to-peak current
- $I_{LRMS}$ is the inductor RMS current

In overloading or load transient conditions, the inductor peak current can increase up to the switch current limit of the device which is typically 8A. The most conservative approach is to choose an inductor with a saturation current rating greater than 8A. Because of the maximum $I_{LPEAK}$ limited by device, the maximum output current that the SCT2460 can deliver also depends on the inductor current ripple. Thus, the maximum desired output current also affects the selection of inductance. The smaller inductor results in larger inductor current ripple leading to a higher maximum output current.

For this design, use $LIR=0.2$ or 0.3, and the inductor value is calculated to be 5uH, the RMS inductor current is 6A and the peak inductor current is 7.2A. The chosen inductor is a WE 744325 55 0, which has a saturation current.
rating of 12A and a RMS current rating of 10A. This also has a typical inductance of 5.5µH at no load and 4.7 µH at 6A load. The inductor DCR is 10.3 mΩ.

**Input Capacitor Selection**

The input current to the step-down DCDC converter is discontinuous, therefore it requires a capacitor to supply the AC current to the step-down DCDC converter while maintaining the DC input voltage. Use capacitors with low ESR for better performance. Ceramic capacitors with X5R or X7R dielectrics are usually suggested because of their low ESR and small temperature coefficients, and it is strongly recommended to use another lower value capacitor (e.g. 0.1uF) with small package size (0603) to filter high frequency switching noise. Place the small size capacitor as close to VIN and GND pins as possible.

The voltage rating of the input capacitor must be greater than the maximum input voltage. And the capacitor must also have a ripple current rating greater than the maximum input current ripple. The RMS current in the input capacitor can be calculated using Equation 14.

\[
I_{\text{CIN RMS}} = I_{\text{OUT}} \sqrt{\frac{V_{\text{OUT}}}{V_{\text{IN}}} \cdot \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}} \right)}
\]  

(14)

The worst case condition occurs at \( V_{\text{IN}}=2\cdot V_{\text{OUT}} \), where:

\[
I_{\text{CIN RMS}} = 0.5 \cdot I_{\text{OUT}}
\]  

(15)

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

When selecting ceramic capacitors, it needs to consider the effective value of a capacitor decreasing as the DC bias voltage across a capacitor increases.

The input capacitance value determines the input ripple voltage of the regulator. The input voltage ripple can be calculated using Equation 16 and the maximum input voltage ripple occurs at 50% duty cycle.

\[
\Delta V_{\text{IN}} = \frac{I_{\text{OUT}}}{f_{\text{SW}} \cdot C_{\text{IN}}} \cdot \frac{V_{\text{OUT}}}{V_{\text{IN}}} \cdot \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}} \right)
\]  

(16)

For this example, three 4.7µF, X7R ceramic capacitors rated for 50 V in parallel are used. And a 0.1 µF for high-frequency filtering capacitor is placed as close as possible to the device pins.

**Bootstrap Capacitor Selection**

A 0.1µF ceramic capacitor must be connected between BOOT pin and SW pin for proper operation. A ceramic capacitor with X5R or better grade dielectric is recommended. The capacitor should have a 10V or higher voltage rating.

**Output Capacitor Selection**

The selection of output capacitor will affect output voltage ripple in steady state and load transient performance.

The output ripple is essentially composed of two parts. One is caused by the inductor current ripple going through the Equivalent Series Resistance ESR of the output capacitors and the other is caused by the inductor current ripple charging and discharging the output capacitors. To achieve small output voltage ripple, choose a low-ESR output capacitor like ceramic capacitor. For ceramic capacitors, the capacitance dominates the output ripple. For simplification, the output voltage ripple can be estimated by Equation 17 desired.

\[
\Delta V_{\text{OUT}} = \frac{V_{\text{OUT}} \cdot (V_{\text{IN}} - V_{\text{OUT}})}{8 \cdot f_{\text{SW}}^2 \cdot L \cdot C_{\text{OUT}} \cdot V_{\text{IN}}}
\]  

(17)

Where

- \( \Delta V_{\text{OUT}} \) is the output voltage ripple
- \( f_{SW} \) is the switching frequency
- \( L \) is the inductance of inductor
- \( C_{OUT} \) is the output capacitance
- \( V_{OUT} \) is the output voltage
- \( V_{IN} \) is the input voltage

Due to capacitor's degrading under DC bias, the bias voltage can significantly reduce capacitance. Ceramic capacitors can lose most of their capacitance at rated voltage. Therefore, leave margin on the voltage rating to ensure adequate effective capacitance. Typically, two 47\( \mu \)F ceramic output capacitors work for most applications.

### Compensation Components

The SCT2460 employs peak current mode control for easy compensation and fast transient response. An external network comprising resistor \( R_4 \), ceramic capacitors \( C_7 \) and optional \( C_6 \) connected to the COMP pin is used for the loop compensation. The equation 18 shows the close-loop small signal transfer function.

\[
H(S) = \left[ A_{EA} \cdot \frac{1}{\left(1 + \frac{s}{2\pi f_{Z1}}\right) \left(1 + \frac{s}{2\pi f_{P1}}\right)} \right] \left[ G_{ISNS} \cdot \frac{V_{OUT}}{I_{OUT}} \cdot \frac{1 + \frac{s}{2\pi f_{Z2}}}{1 + \frac{s}{2\pi f_{P2}}} \right] \frac{V_{FB}}{V_{OUT}} \tag{18}
\]

where
- \( A_{EA} \) is error amplifier voltage gain
- \( G_{ISNS} \) is COMP to SW current trans-conductance, 11.2A/V typically

The DC voltage gain of the loop is given by equation 19.

\[
A_{VDCC} = A_{EA} \cdot G_{ISNS} \cdot \frac{V_{FB}}{I_{OUT}} \tag{19}
\]

The system has two noteworthy poles: one is due to the compensation capacitor \( C_7 \) and the error amplifier output resistor. The other is caused by the output capacitor and the load resistor. These poles as located at:

\[
f_{P1} = \frac{1}{2\pi \cdot R_{OEA} \cdot C_7} = \frac{G_{EA}}{2\pi \cdot A_{EA} \cdot C_7} \tag{20}
\]

\[
f_{P2} = \frac{1}{2\pi \cdot R_{LOAD} \cdot C_{OUT}} = \frac{I_{OUT}}{2\pi \cdot V_{OUT} \cdot C_{OUT}} \tag{21}
\]

where
- \( R_{OEA} \) is error amplifier output resistor
- \( G_{EA} \) is Error amplifier trans-conductance, 300\( \mu \)S typically
- \( R_{LOAD} \) is equivalent load resistor

The system has one zero of importance from \( R_4 \) and \( C_7 \). \( f_{Z1} \) is used to counteract the \( f_{P2} \), and \( f_{Z1} \) located at:

\[
f_{Z1} = \frac{1}{2\pi \cdot C_7 \cdot R_4} \tag{22}
\]

The system may have another important zero if the output capacitor has a large capacitance or a high ESR value. The zero, due to the ESR and the capacitance of the output capacitor is calculated by Equation 23.

\[
f_{Z2} = \frac{1}{2\pi \cdot C_{OUT} \cdot ESR} \tag{23}
\]

In this case, a third pole set by the optional compensation capacitor \( C_6 \) and the compensation resistor \( R_4 \) is used to compensates the effect of the ESR zero. This pole is calculated by Equation 24.
\[ f_{P3} = \frac{1}{2\pi C_6 R_4} \]  \hspace{1cm} (24)

The crossover frequency of converter is shown in Equation 25.

\[ f_c = \frac{V_{FB}}{V_{OUT}} \cdot \frac{G_{EA} \cdot G_{ISNS} \cdot R_4}{2\pi C_{OUT}} \]  \hspace{1cm} (25)

The system crossover frequency, where the feedback loop has unity gain, is important. A lower crossover frequency results in slower line and load transient response. A higher crossover frequency could cause the system unstable. A recommended rule of thumb is to set the crossover frequency to be approximately 1/10 of switching frequency.

The following steps can be followed to calculate the external compensation components. Calculate the compensation resistor \( R_4 \) with Equation 26 once crossover frequency is selected.

\[ R_4 = \frac{V_{OUT}}{V_{FB}} \cdot \frac{2\pi C_{OUT} f_c}{G_{EA} \cdot G_{ISNS}} \]  \hspace{1cm} (26)

Then calculate \( C_7 \) by placing a compensation zero at or before the output stage pole.

\[ C_7 = \frac{R_{LOAD} \cdot C_{OUT}}{R_4} \]  \hspace{1cm} (27)

Determine if the optional compensation capacitor \( C_6 \) is required. Generally, it is required if the ESR zero \( f_{Z2} \) is located less than half of the switching frequency. Then \( f_{P3} \) can be used to cancel \( f_{Z2} \). \( C_6 \) can be calculated with Equation 28.

\[ C_6 = \frac{C_{OUT} \times ESR}{R_4} \]  \hspace{1cm} (28)

Table 3 lists typical values of compensation components for some standard output voltages with various output ceramic capacitors and inductors. The values of the compensation components have been optimized for fast transient responses and good stability. For the conditions not list in Table 3, customers can use Equation 25-Equation 27 to optimize the compensation components.

Layout Guideline

Proper PCB layout is a critical for SCT2460’s stable and efficient operation. The traces conducting fast switching currents or voltages are easy to interact with stray inductance and parasitic capacitance to generate noise and degrade performance. For better results, follow these guidelines as below:

1. Power grounding scheme is very critical because of carrying power, thermal, and glitch/bouncing noise associated with clock frequency. The thumb of rule is to make ground trace lowest impedance and power are distributed evenly on PCB. Sufficiently placing ground area will optimize thermal and not causing over heat area.
2. Place a low ESR ceramic capacitor as close to VIN pin and the ground as possible to reduce parasitic effect.
3. For operation at full rated load, the top side ground area must provide adequate heat dissipating area. Make sure top switching loop with power have lower impedance of grounding.
4. The bottom layer is a large ground plane connected to the ground plane on top layer by vias.
5. Output inductor should be placed close to the SW pin. The area of the PCB conductor minimized to prevent excessive capacitive coupling.
6. The RT/CLK terminal is sensitive to noise so the RT resistor should be located as close as possible to the IC and routed with minimal lengths of trace.
7. UVLO adjust and RT resistors, loop compensation and feedback components should connect to small signal ground which must return to the GND pin without any interleaving with power ground.
8. For achieving better thermal performance, a four-layer layout is strongly recommended.
