36V Vin Quad Channels Automotive PMIC

FEATURES

- Qualified for Automotive Applications
- AEC-Q100 Qualified with the Following Results:
  - Device Temperature Grade 1
- Wide Input Voltage Range: 3.5V-36V
- One Synchronous HV Buck Converter VOUT1:
  - Up to 3A Continuous Output Current
  - Output Voltage of 3.3/3.7/4.6/5V
- Dual Synchronous LV Buck Converters VOUT2, VOUT3:
  - Up to 2A Continuous Output Current
  - Output Voltage Range 0.8V to 2.35V with 50mV Steps
- One Low-Drop Regulator(LDO) VOUT4:
  - Up to 400mA Continuous Output Current
  - Output Voltage: 1.8/2.7/2.8/2.9/3.3V
- +/- 1.5% Feedback Reference Voltage
- Fixed 2.1MHz Switching Frequency with Integrated Frequency Dither for EMI Mitigation
- FCCM/PFM Selectable
- Programmable Power Sequencer for VOUT2, VOUT3 and VOUT4
- RESETB Output for System Management
- External Clock Synchronization
- Simple/QA Watchdog
- Integrated Protection Features:
  - Hiccup Over Current Protection
  - Output Over-voltage/Under-voltage Protection
  - Adjustable Input Voltage Under-voltage Lockout
  - Thermal Shutdown Protection
- Up to 1MHz I2C Interface with Optional Packet Error-Checking (PEC)
- Available in QFN-24 (4mm*4mm)

DESCRIPTION

The SCT61441Q device is a wide input power management IC with four channels output. The device is designed for automotive camera module.

The SCT61441Q integrates one 3A HV Buck, two identical 2A LV Buck and a 400mA LDO. Each channel output is continuously monitored, any over-voltage/under-voltage fault will be detected and the device will enter RESET state. All output voltages are pre-programmed, which saves external feedback divider and minimizes system solution. The switching frequency of HV Buck is 2.1MHz/400kHz selectable. The switching frequency is fixed 2.1MHz for LV buck converters The device features Frequency Spread Spectrum (FSS) with programmable jittering span of the switching frequency and modulation frequency to reduce the conducted EMI.

The device also integrates simple watchdog mode and QA watchdog mode. The dedicated WDI pin allows trigger pulse generated by MCU. Programmable watchdog window is suitable for a wide variety of applications. The RESETB output can be the sequencer of MCU to protect it from device fault.

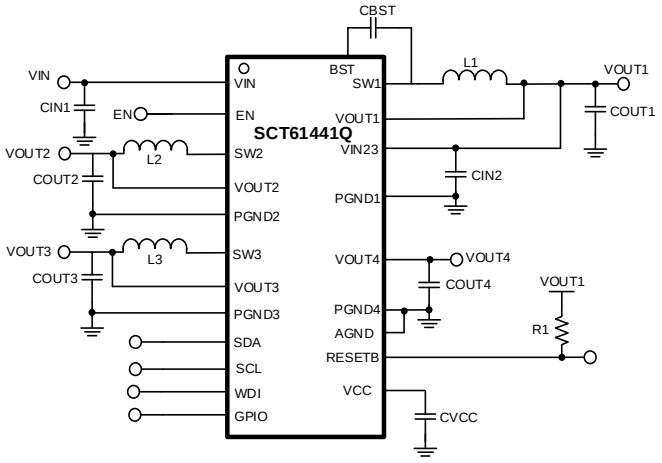
The SCT61441Q device has protection features such as thermal shutdown, short-circuit protection and over-voltage protection. Disabling all outputs via I2C can reduce the quiescent current to 0.85 mA.

The device is available in a QFN-24(4mm*4mm) Package.

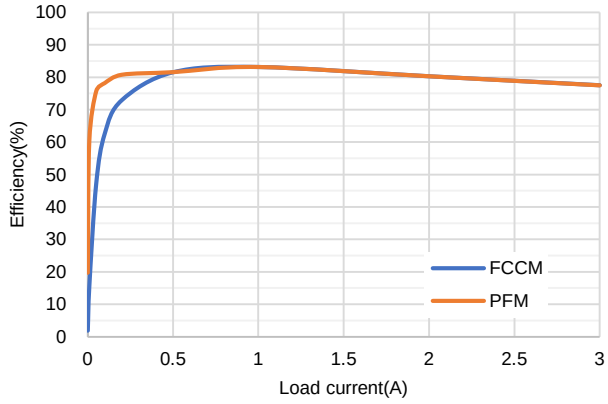
APPLICATIONS

- ADAS
- OMS/DMS
- MCU

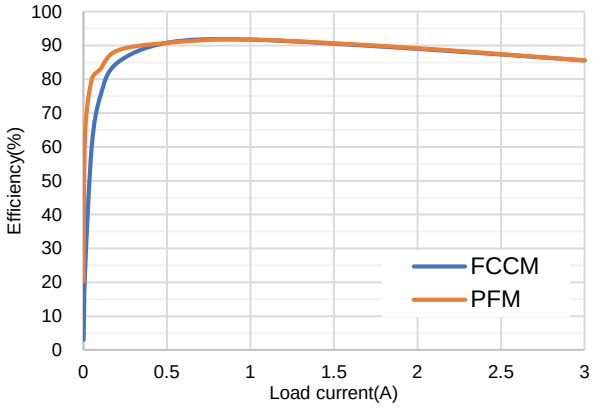
TYPICAL APPLICATION



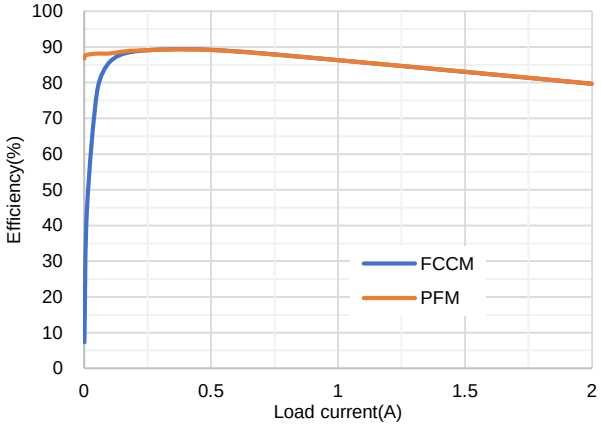
SCT61441Q PMIC Typical Application Circuit



Buck1 Efficiency vs Load Current, V_{OUT1}=3.3V, f_{SW1}=2.1MHz



Buck1 Efficiency vs Load Current, V_{OUT1}=3.3V, f_{SW1}=400kHz



Buck2/3 Efficiency vs Load Current, $V_{OUT2/3}$=1.2V

REVISION HISTORY

NOTE: Page numbers for previous revisions may differ from page numbers in the current version

Revision 1.0: Released to market

DEVICE ORDER INFORMATION

PART NUMBER	PACKAGING TYPE	STANDARD PACK QTY	PACKAGE MARKING	PINS	PACKAGE DESCRIPTION	MSL
SCT61441Q-xxxxFDAR	Tape & Reel	5000	1441Q	24	FCTQFN4x4-24L	1

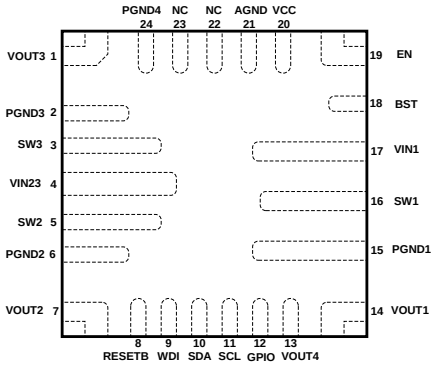
1) "xxxx" is the specific suffix code for different configuration, contact SCT for details

ABSOLUTE MAXIMUM RATINGS

Over operating free-air temperature unless otherwise noted(1)

DESCRIPTION	MIN	MAX	UNIT
VIN, EN	-0.3	42(46V trans 100ms)	V
SW1	-0.3(-1V trans 30ns)	42	V
BST-SW1	-0.3	6	V
Others	-0.3	6	V
Junction temperature(2)	-40	150	°C
Storage temperature T_{STG}	-65	150	°C

PIN CONFIGURATION



Top View: 24-Lead FCTQFN 4mmx4mm

(1) Stresses beyond those listed under Absolute Maximum Rating may cause device permanent damage. The device is not guaranteed to function outside of its Recommended Operation Conditions.

(2) The IC includes over temperature protection to protect the device during overload conditions. Junction temperature will exceed 175°C when over temperature protection is active. Continuous operation above the specified maximum operating junction temperature will reduce lifetime.

PIN FUNCTIONS

NAME	NO.	DESCRIPTION
VOUT3	1	Voltage sense for the output of Buck3. The device regulates VOUT3 voltage to the setting value. Connect this pin to LV Buck3 output voltage via short trace.
PGND3	2	Power ground pin of LV Buck3.
SW3	3	Regulator switching node of LV Buck3. Connect SW3 to an external power inductor.
VIN23	4	Supply voltage for LV Buck2 and Buck3. Must connect this pin to HV Buck1 output voltage directly. Connect a bulk capacitor between this pin to ground. Recommend to put a high-frequency bypass ceramic capacitor to this pin as close as possible.
SW2	5	Regulator switching node of LV Buck2. Connect SW2 to an external power inductor
PGND2	6	Power ground pin of LV Buck2.
VOUT2	7	Voltage sense for the output of Buck2. The device regulates VOUT2 voltage to the setting value. Connect this pin to LV Buck2 output voltage via short trace.
RESETB	8	Open-Drain Reset Output. This output remains low for the programmed hold time after all outputs are built. Connect this pin to high level with a pull-up resistor. Float this pin if not used.
WDI	9	Simple watchdog input.
SDA	10	Serial data line. Open-Drain I/O, connect this pin to high level with a pull-up resistor. Connect this pin to ground if not used.
SCL	11	Serial clock line. Connect this pin to ground if not used.
GPIO	12	The GPIO pin can be configured to either SYNC or WDDIS function. SYNC: The internal oscillator synchronizes to the external clock frequency with PLL. WDDIS: Pull this pin to high level to disable watchdog. Float this pin if not used.
VOUT4	13	LDO output. Connect a bulk capacitor between this pin and ground.

PIN FUNCTIONS (continued)

NAME	NO.	DESCRIPTION
VOUT1	14	Voltage sense for the output of Buck1. The device regulates VOUT1 voltage to the setting value. The device regulates VOUT1 voltage to the value of 3.3V typical. Connect this pin to HV Buck1 output voltage via short trace.
PGND1	15	Power ground pin of HV Buck1.
SW1	16	Regulator switching node of HV Buck1. Connect SW1 to an external power inductor.
VIN	17	Input supply voltage. Connect a local bypass capacitor from VIN pin to GND pin. Path from VIN pin to high frequency bypass capacitor and GND must be as short as possible.
BST	18	Power supply bias for high-side power MOSFET gate driver of Buck1. Connect a 0.1uF capacitor from BST pin to SW pin. Bootstrap capacitor is charged when low-side power MOSFET is on or SW voltage is low.
EN	19	Enable pin. All four outputs will be activated once voltage upon EN reaches high threshold. The input voltage lockout threshold can be adjusted by connecting this pin to the input voltage through a resistor divider. The EN pin is internally pulled-down through 2.1MΩ resistor. Connect to VIN pin if not used.
VCC	20	Output of the internal VCC regulator. Connect a ceramic bypass capacitor from this pin to PGND.
AGND	21	Analog ground pin of device. Connect this pin to power ground directly.
NC	22, 23	Not connected. Connect NC pins to ground.
PGND4	24	Power ground pin. Connect this pin to other PGND pins.

RECOMMENDED OPERATING CONDITIONS

Over operating free-air temperature range unless otherwise noted

PARAMETER	DEFINITION	MIN	MAX	UNIT
V_{IN}	Input voltage range	3.5	36	V
V_{OUT2}	LV Buck2 output voltage range	0.8	2.35	V
V_{OUT3}	LV Buck3 output voltage range	0.8	2.35	V
V_{OUT4}	LDO output voltage range	1.8	3.3	V
T_J	Operating junction temperature	-40	150	°C

ESD RATINGS

PARAMETER	DEFINITION	MIN	MAX	UNIT
V_{ESD}	Human Body Model(HBM), per AEC-Q100-002	-2	+2	kV
	Charged Device Model(CDM), per AEC-Q100-011	-1	+1	kV

THERMAL INFORMATION

PARAMETER	THERMAL METRIC	FCTQFN-24	UNIT
$R_{\theta JA}$	Junction to ambient thermal resistance(1)	39.68	°C/W
Ψ_{JT}	Junction-to-top characterization parameter	1.78	
Ψ_{JB}	Junction-to-board characterization parameter(1)	3.26	
$R_{\theta JC\ (top)}$	Junction to case (top) thermal resistance(1)	24.67	
$R_{\theta JB}$	Junction to board thermal resistance(1)	3.46	

(1) SCT provides $R_{\theta JA}$ and $R_{\theta JC}$ numbers only as reference to estimate junction temperatures of the devices. $R_{\theta JA}$ and $R_{\theta JC}$ are not a characteristic of package itself, but of many other system level characteristics such as the design and layout of the printed circuit board (PCB) on which the SCT61441Q is mounted, thermal pad size, and external environmental factors. The PCB board is a heat sink that is soldered to the leads and thermal pad of the SCT61441Q. Changing the design or configuration of the PCB board changes the efficiency of the heat sink and therefore the actual $R_{\theta JA}$ and $R_{\theta JC}$.

ELECTRICAL CHARACTERISTICS

V_{IN}=12V, T_J=-40°C~150°C, typical values are tested under 25°C.

FUNCTIONAL BLOCK DIAGRAM

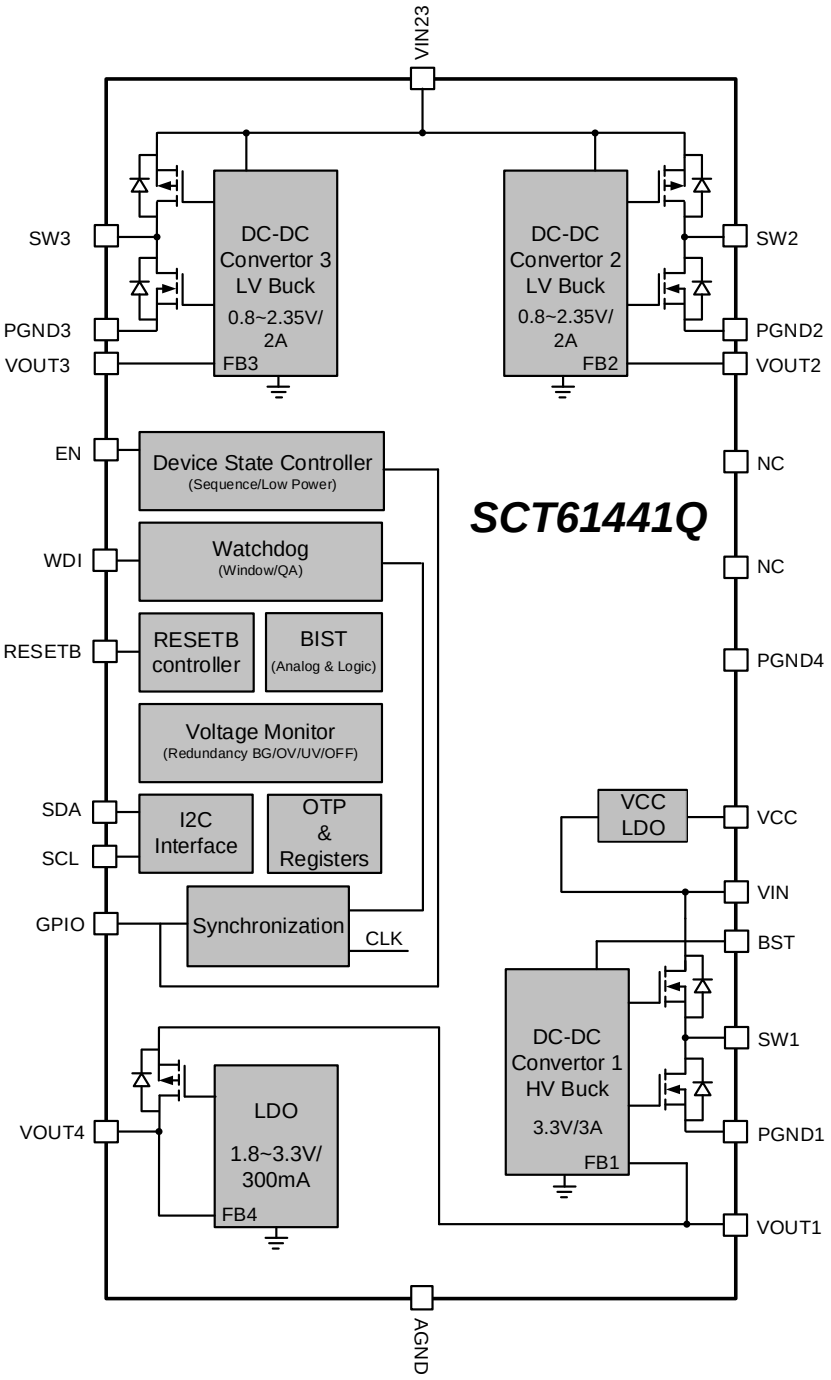

Figure 1. Functional Block Diagram

OPERATION

Overview

The SCT61441Q device is a wide input power management IC with quad channels output. The device is designed for camera modules in automotive ADAS vision and DMS/OMS applications. The SCT61441Q integrates one 3A HV Buck, two identical 2A LV Buck and a 400mA LV Low-Drop Regulator(LDO). Each channel output is continuously monitored, any over-voltage/under-voltage fault will trigger RESETB pull low. Any deep over-voltage/under-voltage will be detected and the device will enter DEEPSAFE state. All output voltages are pre-programmed, which saves external feedback divider and minimizes system solution. The switching frequency of HV Buck is 2.1MHz/400kHz selectable. The switching frequency is fixed 2.1MHz for LV buck converters. The device features Frequency Spread Spectrum (FSS) with programmable jittering span of the switching frequency and modulation frequency to reduce the conducted EMI.

The device also integrates simple watchdog mode and QA watchdog mode. The dedicated WDI pin allows trigger pulse generated by MCU. Programmable watchdog window is suitable for a wide variety of applications. The RESETB output can be the sequencer of MCU to protect it from device fault.

The SCT61441Q device has protection features such as thermal shutdown, short-circuit protection and over-voltage/under-voltage protection. Disabling all outputs via I2C can reduce the quiescent current to 0.85 mA.

Operating State Machine

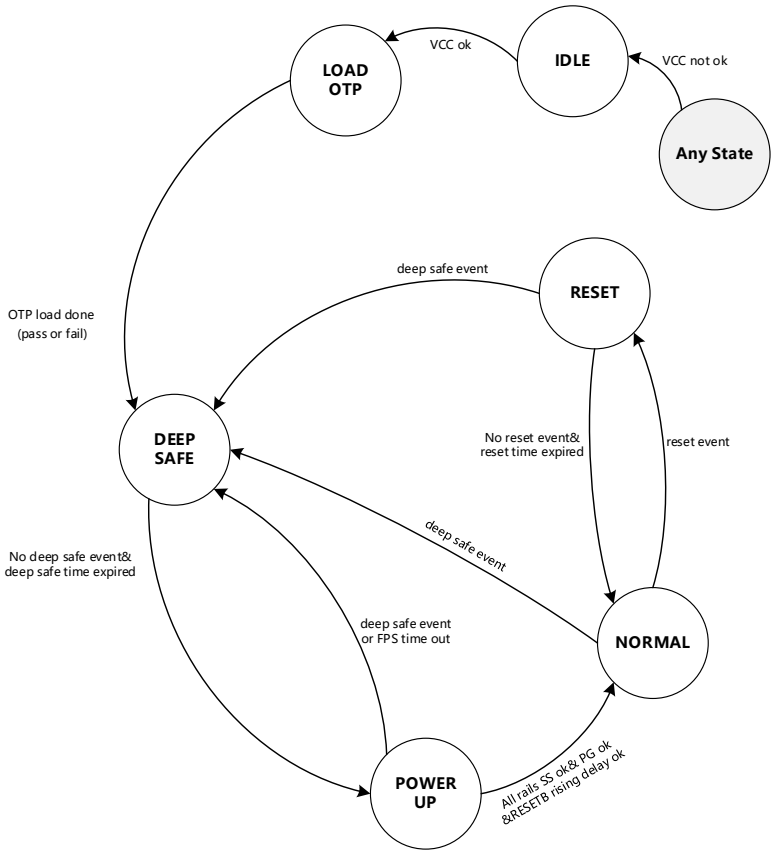

Figure 2. Operating State Transitions

Table 1. State and Function Matrix Table

State	Function										
	I2C	OTP load	Register reset	HV BUCK1	LV BUCK2	LV BUCK3	LDO4	Watchdog	OCP	DOVP/DUVP detect	TSD
IDLE	OFF	OFF	ON	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
LOADOTP	OFF	ON	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
DEEPSAFE	ON	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	ON
POWERUP	ON	OFF	OFF	UP	UP	UP	UP	OFF	ON	ON	ON
NORMAL	ON	OFF	OFF	ON	ON	ON	ON	ON	ON	ON	ON
RESET	ON	OFF	OFF	ON	ON	ON	ON	OFF	ON	ON	ON

Table 2. State and Functional Pin Matrix Table

State	RESETB
IDLE	Tri-state
LOADOTP	LOW
DEEPSAFE	LOW
POWERUP	LOW
NORMAL	HIGH
RESET	LOW

IDLE State

The device will enter IDLE state whenever VCC is below the UVLO threshold. All functional blocks are disabled and all registers are reset. The device will exit IDLE state and jump to LOADOTP state only when VCC reaches its rising threshold 2.8V.

LOADOTP State

Once the device enters OTPLOAD state, the OTP CRC mechanism will be activated and check through all data. Only when CRC check is passed, the device will load all non-volatile memory to register. The CRC check result will be recorded in register **SYS_STATE**.

DEEPSAFE State

In DEEPSAFE state, all power rails are shut off and indicator pins are pulled low. Regardless of current state, the device will always jump to DEEPSAFE state when any deep safe event occurs. I2C interface and thermal shutdown protection are activated. MCU is able to communicate with device through I2C and read fault register to locate fault. If there is no deep safe event and deep safe timeout is expired, the device will enter POWERUP state automatically.

Deep safe events are listed as below:

- VOUT1's output is out of deep OV/UV protection range or OCP
- VOUT2's output is out of deep OV/UV protection range or OCP
- VOUT3's output is out of deep OV/UV protection range or OCP
- VOUT4's output is out of deep OV/UV protection range or OCP
- Tj reaches Thermal Shutdown Point
- VIN/EN UVLO
- VCC OVP
- VIN OVP
- RESETB Stuck
- Loss of ground

POWERUP State

In POWERUP state, all rails will start-up following a dedicated sequence. Since the HV buck VOUT1 is the power supply for the other channels, VOUT1 is always set to start-up first. Then the other channels will rise after turn on

delay time respectively. The turn on delay time for each is independent and can be adjusted via changing register **CONFIG_PU1** and **CONFIG_PU2**, thus flexible sequence is available. Deep OV/UV protection is activated to protect channels from destructive OV/UV risk. If all channels finish soft-start and they are within power good range, the RESETB rising timer begins. Once the timer is expired, the device will enter NORMAL state and RESETB will output high. If deep safe event occurs, the state will transit to DEEPSAFE state directly.

NORMAL State

The NORMAL state is the normal running of device with all outputs on. The RESETB pin is released after specific delay time upon entering this state. If watchdog is enabled by register **CONFIG_WD3**, watchdog window will start after setting delay time. The delay time is configured by **WD_1UD[2:0]** in register **CONFIG_WD3**. MCU should feed the watchdog via WDI pin or write answer to specified register periodically. When operating in NOMRAL state, the device will go to RESET state once reset event occurs.

RESET State

All outputs keep on in this state, the device will transit from NORMAL state to RESET state when any of below reset event occurs:

- VOUT1's output is out of OV/UV protection range
- VOUT2's output is out of OV/UV protection range
- VOUT3's output is out of OV/UV protection range
- VOUT4's output is out of OV/UV protection range
- Watchdog Failure

When the device enters RESET state, the RESETB pin will assert for a holding time. The device will go back to NORMAL state automatically once the holding time is expired and no reset event, which can be configured in register **CONFIG_T1** via I2C. Upon entering NOMRAL state Watchdog failure counter will be reset and start running again. Then MCU should feed the watchdog again.

VIN and EN UVLO

When the VIN pin voltage rises above 3.2V and the EN pin voltage exceeds the enable threshold of 1.2V, the device is enabled. And the device disables when the VIN pin voltage falls below 2.8V or when the EN pin voltage is below 1.0V.

EN pin is connected internally to ground allows the device to be disabled when EN pin is floating to simplify the system design.

High Efficiency Regulators

The switching frequency of HV Buck is 2.1MHz/400kHz selectable. All the LV bucks employ 2.1MHz fixed frequency peak current mode control. Forced continuous conduction mode (FCCM) allows the device to have a high output performance when light load. Built-in UVLO ensures all channels are capable of regulated output under the operating VIN range. Soft-start is fixed at 1ms for all channels. VOUT1 will always be the firstly built rail after power on, the other rails can be configured with range 0ms to 75ms turn on delay. Then the device can achieve a variety of sequence to fit power system.

The VOUT1 is a HV synchronous buck converter directly power from VIN pin. It's regulated at 3.3V with up to 3A continuous current. An external 100nF ceramic bootstrap capacitor between BST and SW1 pin powers high-side power MOSFET gate driver. The bootstrap capacitor voltage is charged from an integrated voltage regulator when high-side power MOSFET is off and low-side power MOSFET is on. Note VOUT1 is the power supply for VOUT2/3/4.

The VOUT2 and VOUT3 are two identical LV synchronous buck converter power by VOUT1. Their output can be configured via I2C range from 0.8V to 2.35V with 50mV step. Each is capable of 2A continuous current. To further improve the EMI performance, the VOUT2 and VOUT3 will operate with 180° phase-shifted clock.

The VOUT4 is a low-drop regulator(LDO) also powered by VOUT1. The LDO output is factory-programmed at 1.8V, 2.7V, 2.8V, 2.9V or 3.3V with up to 400mA continuous output current.

The converters have proprietary designed gate driver scheme to resist switching node ringing without sacrificing MOSFET turn-on and turn-off time, which further erases high frequency radiation EMI noise caused by the MOSFETs hard switching.

Each output voltage is continuously monitored during operation, the OV/UV threshold can be adjusted independently in register **CONFIG_PGSEL1** and **CONFIG_PGSEL2**.

Deep Over Voltage Protection

If any output exceeds the deep over voltage protection threshold 115%, all outputs will shut off for the hiccup time. When hiccup ends, the normal power up sequence will start again following turn on delay setting in register. When entry hiccup, the output discharge will operate during the hiccup time. The threshold can be configured by bits **DEEP_OVP_SEL[1:0]**.

Deep Under Voltage Protection

If an output falls below the deep under voltage protection threshold 75%, all outputs will shut off for the hiccup time. When hiccup ends, the normal power up sequence will start again following turn on delay setting in register. When entry hiccup, the output discharge will operate during the hiccup time. The threshold can be configured by bits **DEEP_UVP_SEL[1:0]**.

Thermal Shutdown

The thermal shutdown protects the device from the damage during excessive heat and power dissipation conditions. Once the junction temperature exceeds 175°C, the internal thermal sensor stops power MOSFETs switching. When the junction temperature falls below 155°C, the device will restart with internal soft start phase.

Over Current Protection (OCP)

The converters implement over current protection with cycle-by-cycle limiting high-side MOSFET peak current and also low-side MOSFET valley current to avoid inductor current running away during unexpected overload and hiccup protection in output hard short condition. When overload or hard short happens, the converter cannot provide output current to satisfy loading requirement even though the inductor current has already been clamped at over current limitation. Thus, output voltage drops below regulated voltage continuously. When peak current point is kicked for continuous 32 times, the converter stops switching, the device will jump to DEEPSAFE state. The hiccup protection mode greatly reduces the average short circuit current to alleviate thermal issues and protect the regulator.

Frequency Spread Spectrum

To meet CISPR and automotive EMI compliances, the SCT61441Q implements Frequency Spread Spectrum (FSS) function. The FSS circuitry shifts the 2.1MHz switching frequency within dedicated range and period triangular or pseudo modulation. Therefore, the SCT61441Q can guarantee that the switching frequency does not drop into the 1.8MHz AM band limit.

Frequency Foldback

To avoid meeting minimum on time, the HV buck VOUT1 will reduce switching frequency actively when input voltage rising high. Other channel's frequency is unchanged.

When VIN greatly drops and minimum off time of HV buck VOUT1 is kicked, the VOUT1 enter dropout mode and also reduce its frequency to get max output.

RESETB Indicator

The RESETB indicator will assert when reset event occurs. It will reset MCU if it fails to feed watchdog, MCU then can reloading program to ensure the program run well. The RESETB pin is an open-drain output and can be connected to various I/O level through pull-up resistor. The reset event mapping to RESETB pin can be configured through changing the register **RSTMAP**.

Active Output Discharge

Once any output is shutoff due to deep safe events or disabled by I2C command, there is an active output discharge path will be turned on for each channel.

Synchronization and Watchdog Disable

The device can be synchronized to an external clock when GPIO pin is set to SYNC. The external clock must be connected between the GPIO pin and ground. The synchronization frequency range is from 1.5MHz to 3MHz. A square wave clock signal to GPIO pin must have high level no lower than 1.2V, low level no higher than 0.6V, and pulse width larger than 15ns.

When GPIO pin is set to WDDIS, if a high level on GPIO pin stays longer than 20μs, the watchdog will be disabled. Only when connecting low level to GPIO pin can release the watchdog, there is an internal 1.8MΩ pull-down resistor.

Watchdog

During NORMAL state, the watchdog can monitor the MCU with programmable cycle. Everytime the device enters NORMAL state and RESETB pin is released, the watchdog will be activated if WDDIS pin is low and bit **WD_EN[0]**=1b. There will be extension cycles if **WD_EN[0]**=1b when entering NORMAL state, which is used to wait MCU's program loading process and can be configured by bit **WD_1UD[2:0]**. During the close window of first update extension, any WDI or **WD_KEY** signals will be ignored and WD error counter keeps zero.

Simple Watchdog

If **WD_MODE[0]** = 1, the device will implement simple watchdog, the MCU should provide trigger pulse to WDI pin or write any byte to specific register **WD_KEY** within the open window. The length of open window and closed window can be configured by I2C. A correct watchdog trigger will restart the whole window cycle immediately. Giving pulse or writing byte to register **WD_KEY** during the closed window will result in **WD_UV[0]** violation and will restart the whole window cycle immediately. If MCU doesn't send high pulse or write byte to **WD_KEY** before the whole window is expired, **WD_EXP[0]** violation occurs. Any violation will make the WD error counter plus one. When WD error counter reaches the **WD_FAIL_CNT[0]** (1 or 2 times), a WD Failure is reported and device enters RESET state.

QA Watchdog

If **WD_MODE[0]** = 0, the device will implement Question and Answer (QA) watchdog and signals on WDI pin are ignored. In QA watchdog mode, MCU should read register **WD_KEY** to get the answer through I2C. Then MCU response the watchdog in open window through writing the specific answer to register **WD_KEY**. A correct watchdog trigger will refresh the whole window cycle immediately and the **WD_KEY** register being updated. Writing the incorrect answer to the **WD_KEY** will result in the value written being ignored and a **WD_LFSR[0]** violation. Writing the correct response during a closed window will result in the write being ignored and a **WD_UV[0]** violation. If MCU doesn't write byte to **WD_KEY** and the whole window is expired, **WD_EXP[0]** violation occurs. LFSR polynomial: x8 + x6 + x5 + x4 + 1. Any violation except **WD_LFSR[0]** violation will make the WD error counter plus one. When WD error counter reaches the **WD_FAIL_CNT[0]** (1 or 2 times), a WD Failure is reported and device enters RESET state.

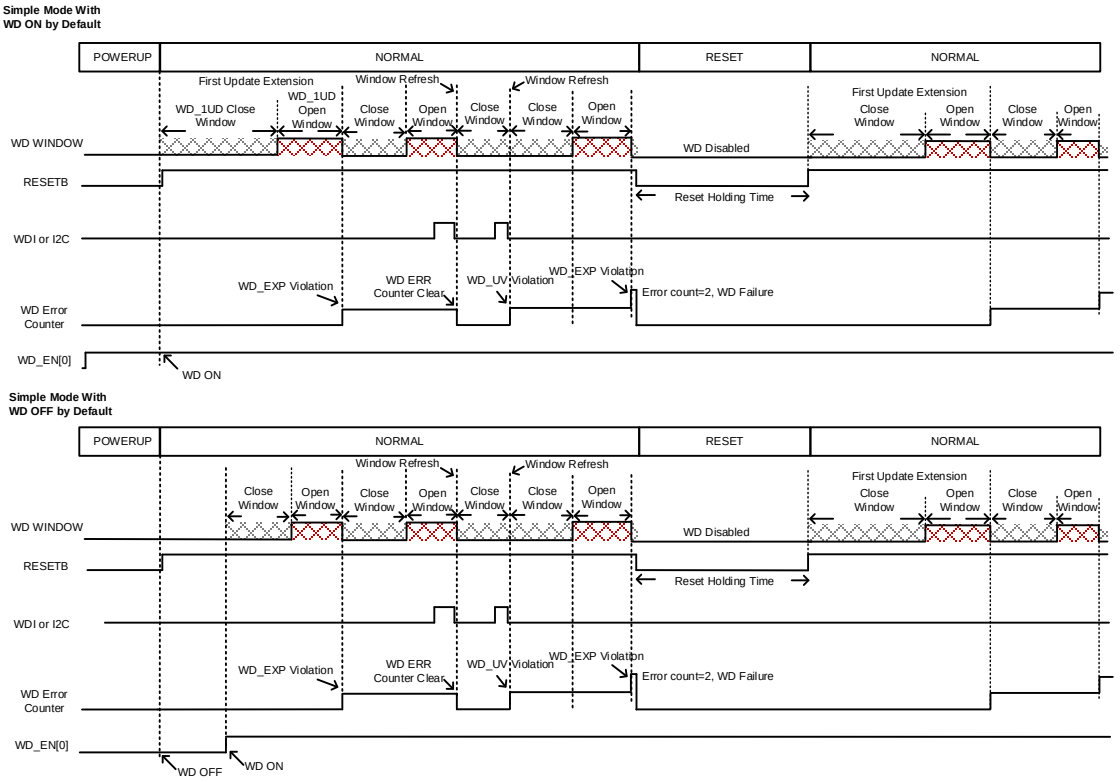

Figure 3a. Simple Watchdog Error Timing

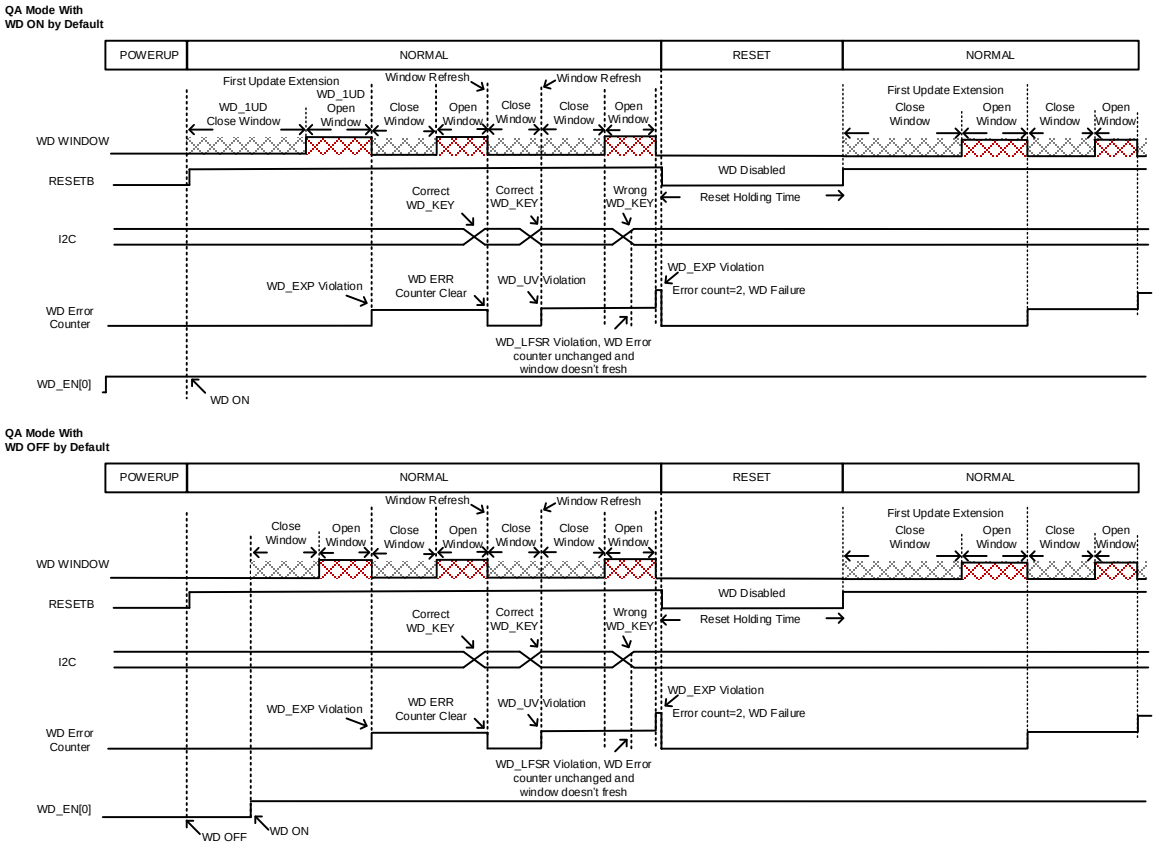

Figure 3b. QA Watchdog Error Timing

I2C Interface

The SCT61441Q integrates a two-wire serial interface for bidirectional communications between the device and the master through bus. The I2C protocol defines two bus lines, the serial data line (SDA) and the serial clock line (SCL). The SCT61441Q is always assigned a unique chip address and operates as a slaver, the master drives the SCL line and transfer bidirectional data through SDA line. Both the SCL and SDA lines need a pull-up resistor connected to bus voltage since HIGH state is the default state when bus is idle. The SCT61441Q supports Standard-mode (up to 100 kHz), Fast-mode (up to 400 kHz), Fast-mode Plus (up to 1 MHz). The internal filtering ignores spikes and noises on the bus line to preserve data integrity. The maximum capacitive load for each bus line is given in Electrical Characteristic thus the number of interfaces is limited.

Data Validity

The data on the SDA line must be stable during the HIGH period of the clock. The HIGH or LOW state of the data line can only change when the clock signal on the SCL line is LOW.

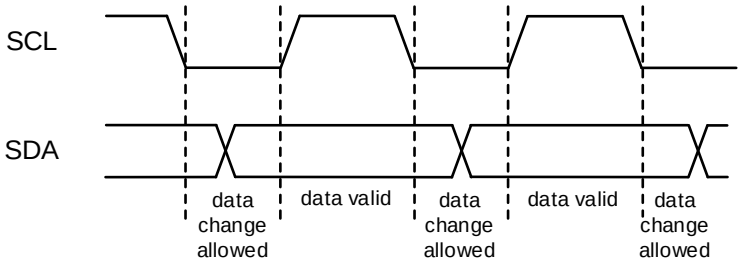

Figure 4. Data Validity Diagram

START and STOP Conditions

The data transfer always generates START and STOP conditions to announce the process. A HIGH to LOW transition on the SDA line while SCL is HIGH defines a START condition. A LOW to HIGH transition on the SDA line while SCL is HIGH defines a STOP condition. Both the START and STOP conditions are generated by master on bus.

The bus is considered to be busy after START condition and released after STOP condition. A repeated START condition during transmission is also valid and will be regard as a new START condition.

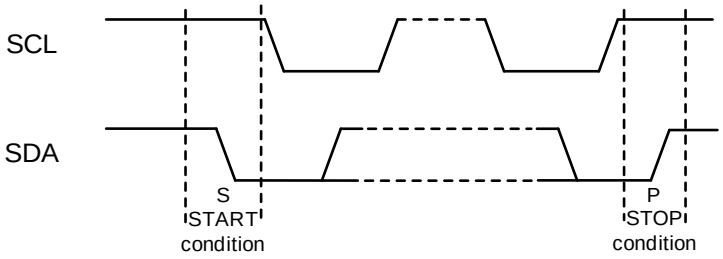

Figure 5. START and STOP Conditions Diagram

Data Transmission

The transferred byte consists of eight bits with the Most Significant Bit (MSB) first. After each byte is transferred, the master will release the SDA line and generate the ninth acknowledge clock pulse on SCL line. The SCT61441Q will pull the SDA line LOW during this acknowledge clock, to announce a successful reception and next byte may be sent. If the master is receiver and the last byte is received, it still generates the ninth acknowledge clock pulse but SDA line will not be pulled LOW. It's called not acknowledge signal and indicates the end of transmission.

After the START condition, the master must send a slave address as the first addressing byte. The slave address is seven bits long followed by an eighth R/W bit. The R/W bit defines the data direction. Set the R/W bit to 0 to indicate write command, and a 1 indicates read command. The slave address is factory-programmed between 0x38 through 0x3B, see DEVICE ORDER INFORMATION for details.

Packet Error Checking (PEC)

The SCT61441Q supports optional packet error checking (PEC) byte during the I2C communication. PEC can significantly increase fault coverage on the I2C interface. The PEC byte is implemented through CRC-8 polynomial of x8 + x2 + x +1. The PEC byte does not take ACK, NACK, START, STOP, Repeated START bits into calculation. The PEC byte is calculated on the register address and data byte over the entire message from the first START condition, note that the slave address is removed both in write and read command. When PEC is enabled, the device will reject the write command if the master send an incorrect PEC byte. When in read mode with PEC enabled, the master should acknowledge the data byte thus then the device will send the PEC byte. The PEC can be configured by **PEC_EN** in register **CONFIG_FSS**.

Write Data Format

A write to the device includes transmission of the following:

- START condition
- Slave address with the write bit set to 0
- 1 byte of data to register address
- 1 byte of data to the command register
- STOP condition

Read Data Format

A read from the device includes the following:

- Transmission of a START condition
- Slave address with the write bit set to 0
- 1 byte of data to register address
- Restart condition
- Slave address with read bit set to 1
- 1 byte of data to the command register
- STOP condition

Figure 6 illustrates the proper format for one frame.

APPLICATION INFORMATION

Typical Application

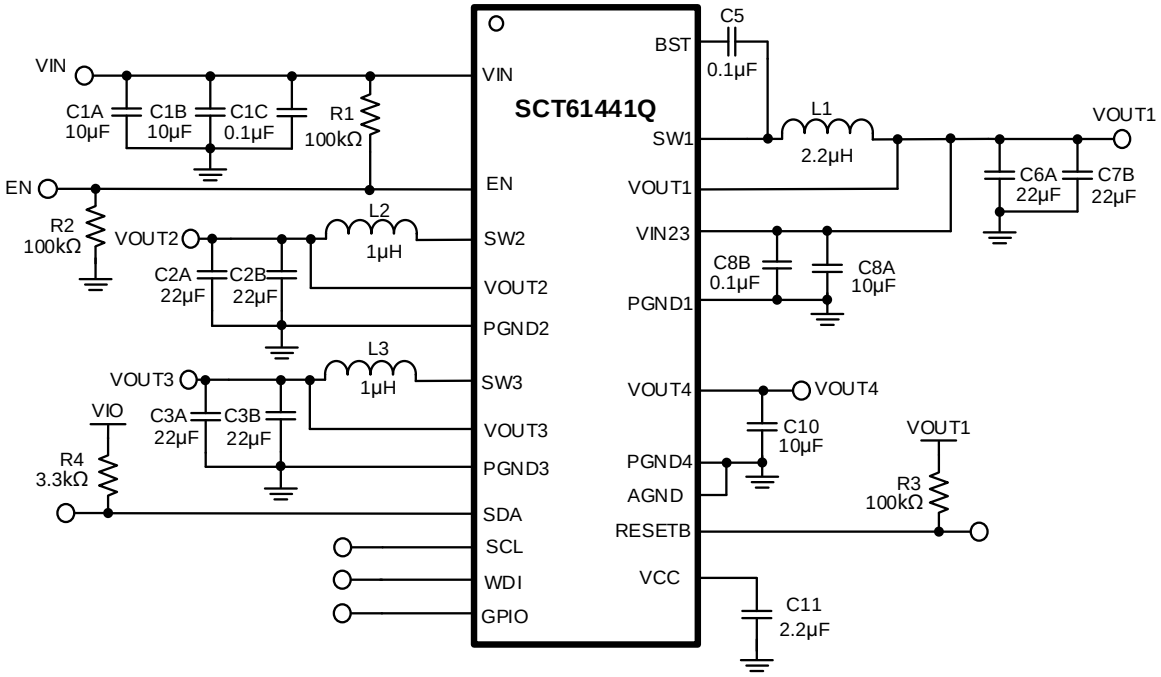

Figure 8. Application Schematic, 3.5V to 36V, PMIC Regulator at 2.1MHz

Design Parameters

Design Parameters	Example Value
Input Voltage	12V Normal 3.5V to 36V
Output Voltage	VOUT1: 3.3V VOUT2: 1.2V VOUT3: 1.8V VOUT4: 2.8V
Maximum Output Current	VOUT1: 3A (in total) VOUT2: 2A VOUT3: 2A VOUT4: 400mA
Switching Frequency	2.1MHz
Output Voltage Ripple (peak to peak)	VOUT1: 10mV VOUT2: 5mV VOUT3: 5mV

Under Voltage Lock-Out

An external voltage divider network of R_1 from the input to EN pin and R_2 from EN pin to the ground can set a higher input voltage's Under Voltage Lock-Out (UVLO) threshold. The UVLO has two thresholds, one for power up when the input voltage is rising and the other for power down or brown outs when the input voltage is falling. Use Equation 1 and Equation 2 to calculate the values of R_1 and R_2 resistors.

$$V_{rise} = \left(1 + \frac{R_1}{R_2}\right) * V_{ENrise} \quad (1)$$

$$V_{fall} = \left(1 + \frac{R_1}{R_2}\right) * V_{ENfall} \quad (2)$$

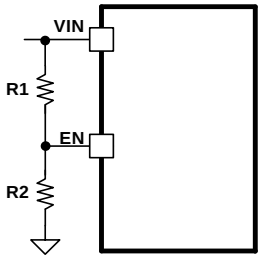

Figure 9. System UVLO by enable divide

where

- V_{rise} is rising threshold of Vin UVLO
- V_{fall} is falling threshold of Vin UVLO
- V_{ENrise} is rising threshold of EN UVLO
- V_{ENfall} is falling threshold of EN UVLO

Inductor Selection

There are several factors should be considered in selecting inductor such as inductance, saturation current, the RMS current and DC resistance(DCR). Larger inductance results in less inductor current ripple and therefore leads to lower output voltage ripple. However, the larger value inductor always corresponds to a bigger physical size, higher series resistance, and lower saturation current. A good rule for determining the inductance to use is to allow the inductor peak-to-peak ripple current to be approximately 20%~40% of the maximum output current.

For a buck converter, the peak-to-peak ripple current in the inductor I_{LPP} can be calculated as in Equation 3.

$$I_{LPP\_BUCK} = \frac{V_{OUT} * (V_{IN} - V_{OUT})}{V_{IN} * L * f_{SW}} \quad (3)$$

Where

- I_{LPP_BUCK} is the inductor peak-to-peak current of buck
- L is the inductance of inductor
- f_{SW} is the switching frequency
- V_{OUT} is the output voltage
- V_{IN} is the input voltage

Since the inductor-current ripple increases with the input voltage, so the maximum input voltage in application is always used to calculate the minimum inductance required. Use Equation 4 to calculate the inductance value.

$$L_{MIN} = \frac{V_{OUT}}{f_{SW} * LIR * I_{OUT(max)}} * \left(1 - \frac{V_{OUT}}{V_{IN(max)}}\right) \quad (4)$$

Where

- L_{MIN} is the minimum inductance required
- $V_{IN(max)}$ is the maximum input voltage
- $I_{OUT(max)}$ is the maximum DC load current
- LIR is coefficient of I_{LPP} to I_{OUT}

The total current flowing through the inductor is the inductor ripple current plus the output current. When selecting an inductor, choose its rated current especially the saturation current larger than its peak operation current and RMS current also not be exceeded. Therefore, the peak switching current of inductor, I_{LPEAK} and I_{LRMS} can be calculated as in equation 5 and equation 6.

$$I_{LPEAK} = I_{OUT} + \frac{I_{LPP}}{2} \quad (5)$$

$$I_{LRMS} = \sqrt{(I_{OUT})^2 + \frac{1}{12} * (I_{LPP})^2} \quad (6)$$

Where

- I_{LPEAK} is the inductor peak current
- I_{OUT} is the DC load current
- I_{LPP} is the inductor peak-to-peak current
- I_{LRMS} is the inductor RMS current

In overloading or load transient conditions, the inductor peak current can increase up to the switch current limit of the device. The most conservative approach is to choose an inductor with a saturation current rating greater than peak current limit. Because of the maximum I_{LPEAK} limited by device, the maximum output current that the device can deliver also depends on the inductor current ripple. Thus, the maximum desired output current also affects the selection of inductance. The smaller inductor results in larger inductor current ripple leading to a lower maximum output current.

Input Capacitor Selection

The input current to the step-down DCDC converter is discontinuous, therefore it requires a capacitor to supply the AC current to the step-down DCDC converter while maintaining the DC input voltage. Use capacitors with low ESR for better performance. Ceramic capacitors with X5R or X7R dielectrics are usually suggested because of their low ESR and small temperature coefficients, and it is strongly recommended to use another lower value capacitor (e.g. 0.1uF) with small package size (0603) to filter high frequency switching noise. Place the small size capacitor as close to VIN and GND pins as possible.

For buck converter, the voltage rating of the input capacitor must be greater than the maximum input voltage. And the capacitor must also have a ripple current rating greater than the maximum input current ripple. The RMS current in the input capacitor can be calculated using Equation 7.

$$I_{CINRMS} = I_{OUT} * \sqrt{\frac{V_{OUT}}{V_{IN}} * (1 - \frac{V_{OUT}}{V_{IN}})} \quad (7)$$

The worst case condition occurs at V_{IN}=2*V_{OUT}, where:

$$I_{CINRMS} = 0.5 * I_{OUT} \quad (8)$$

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

When selecting ceramic capacitors, it needs to consider the effective value of a capacitor decreasing as the DC bias voltage across a capacitor increasing.

The input capacitance value determines the input ripple voltage of the regulator. The input voltage ripple can be calculated using Equation 9 and the maximum input voltage ripple occurs at 50% duty cycle.

$$\Delta V_{IN} = \frac{I_{OUT}}{f_{SW} * C_{IN}} * \frac{V_{OUT}}{V_{IN}} * (1 - \frac{V_{OUT}}{V_{IN}}) \quad (9)$$

Bootstrap Capacitor Selection

A 0.1μF ceramic capacitor must be connected between BST pin and SW1 pin for proper operation. A ceramic capacitor with X5R or better grade dielectric is recommended. The capacitor should have a 10V or higher voltage rating.

Output Capacitor Selection

The selection of output capacitor will affect output voltage ripple in steady state and load transient performance.

For buck converter, the output ripple is essentially composed of two parts. One is caused by the inductor current ripple going through the Equivalent Series Resistance ESR of the output capacitors and the other is caused by the inductor current ripple charging and discharging the output capacitors. To achieve small output voltage ripple, choose a low-ESR output capacitor like ceramic capacitor. For ceramic capacitors, the capacitance dominates the output ripple. For simplification, the output voltage ripple can be estimated by Equation 10 desired.

$$\Delta V_{OUT\_BUCK} = \frac{V_{OUT} * (V_{IN} - V_{OUT})}{8 * {f_{SW}}^2 * L * C_{OUT} * V_{IN}} \quad (10)$$

Where

- ΔV_{OUT_BUCK} is the output voltage ripple of buck converter
- f_{SW} is the switching frequency
- L is the inductance of inductor
- C_{OUT} is the output capacitance
- V_{OUT} is the output voltage
- V_{IN} is the input voltage

Due to capacitor's degrading under DC bias, the bias voltage can significantly reduce capacitance. Ceramic capacitors can lose most of their capacitance at rated voltage. Therefore, leave margin on the voltage rating to ensure adequate effective capacitance. Typically, two 10μF ceramic output capacitors work for most applications.

Table 3. Recommended BOM for Typical Application

Output Rail	Frequency (MHz)	L (uH)	Input Capacitor (uF)	Output Capacitor (uF)
Buck1	2.1	2.2	2 x 10+1 x 0.1	2 x 22
Buck2	2.1	1	10+1 x 0.1	2 x 22
Buck3	2.1	1		2 x 22
LDO4	-	-	-	10
VCC	-	-	-	2.2

Application Waveforms

Vin=12V, V_{OUT1}=3.3V, V_{OUT2}=1.1V, V_{OUT3}=1.5V, V_{OUT4}=2.8V, unless otherwise noted

Layout Guideline

Proper PCB layout is a critical for device's stable and efficient operation. The traces conducting fast switching currents or voltages are easy to interact with stray inductance and parasitic capacitance to generate noise and degrade performance. For better results, follow these guidelines as below:

1. Power grounding scheme is very critical because of carrying power, thermal, and glitch/bouncing noise associated with clock frequency. The rule of thumb is to make ground trace lowest impendence and power are distributed evenly on PCB. Sufficiently placing ground area will optimize thermal and not causing over heat area.

2. Make sure the ground path between VIN capacitor and PGND1 pin is shortest with lowest impendence.

3. Place a low ESR ceramic capacitor as close to VIN1 and VIN23 pin and the ground as possible to reduce parasitic effect.

4. For operation at full rated load, the top side ground area must provide adequate heat dissipating area. Make sure top switching loop with power have lower impendence of grounding.

5. The bottom layer is a large ground plane connected to the ground plane on top layer by vias. The power pad should be connected to bottom PCB ground planes using multiple vias.

6. Output inductor should be placed close to the SW pin. The switching area of the PCB conductor minimized to prevent excessive capacitive coupling.

7. EN UVLO adjust resistors and feedback trace should connect to small signal ground which must return to the GND pin without any interleaving with power ground.

8. For achieving better thermal performance, a four-layer layout is strongly recommended.

[6]	WD_SCALE	W/R	Watchdog Clock Divider Scale	0 = 128us 1 = 128us*64
[5:0]	WD_CLK	W/R	Watchdog Clock Divider	tWDCLK = (WD_CLK[5:0]+1) x WD_SCALE

CONFIG_WD2 [7:0]				
ADDRESS: 0x14				
BITS	**FIELD**	**TYPE**	**DESCRIPTION**	**DECODE**
[7:4]	WD_TCLOSE	W/R	Watchdog Close Window Duration Time. Sets the number of watchdog clock cycles before the open window starts.	tWD_CLOSE = tWDCLK x (WD_ TCLOSE [3:0]+1) x 8
[3:0]	WD_TOPEN	W/R	Watchdog Open Window Duration Time. Sets the number of watchdog clock cycles after the close window finishes.	tWD_OPEN = tWDCLK x (WD_ TOPEN[3:0]+1) x 8

CONFIG_WD3 [7:0]				
ADDRESS: 0x15				
BITS	**FIELD**	**TYPE**	**DESCRIPTION**	**DECODE**
[7:5]	RESERVED	R	/	/
[4]	WD_FAIL_CNT	W/R	Watchdog Failure counter config. When Watchdog failure times reach the counter, report to RESETB and status register.	0 = 1 time 1 = 2 times
[3]	WD_EN	W/R	Watchdog Enable	0 = Disabled 1 = Enabled
[2:0]	WD_1UD	W/R	First Update Extension. Sets the number of extra watchdog window cycles after POR to the normal watchdog window.	t1STWD_CLOSE = tWD_CLOSE x (WD_1UD [2:0] + 1) t1STWD_OPEN = tWD_OPEN x (WD_1UD [2:0] + 1)

WD_KEY [7:0]				
ADDRESS: 0x16				
BITS	**FIELD**	**TYPE**	**DESCRIPTION**	**DECODE**
[7:0]	WD_KEY	W/R	Watchdog Key.	The current key can be read from this register. To update the watchdog, the next value in the sequence must be written to this register. If configured as a simple windowed watchdog, writing any value to the WDKEY register will refresh the watchdog and the value written will be ignored.

				If configured as a QA watchdog, writing the incorrect response to the WDKEY register will result in the value written being ignored and a WD_LFSR violation. Writing the correct response in QA mode during an open window will result in a refresh and the WDKEY register being updated. Writing the correct response in QA mode during a closed window will result in the write being ignored and a WD_UV violation. LFSR polynomial: x8 + x6 + x5 + x4 + 1
