FEATURES
- Wide Input Range: 4.5V-60V
- Continuous Output Current: 1A
- 0.765V ±2.5% Feedback Reference Voltage
- Integrated 500mΩ High-Side
- Low Quiescent Current: 80uA
- Pulse Skipping Mode (PSM) in light load
- 80ns Minimum On-time
- 6ms Internal Soft-start Time
- Internal compensation
- Switching Frequency 480KHz
- Precision Enable Threshold for Programmable Input Voltage Under-Voltage Lock Out Protection (UVLO) Threshold and Hysteresis
- Low Dropout Mode Operation
- Over-voltage and Over-Temperature Protection
- Available in an TSOT23-6L Package

DESCRIPTION
The SCT2613 is 1A buck converter with wide input voltage, ranging from 4.5V to 60V, which integrates an 500mΩ high-side MOSFET. The SCT2613, adopting the peak current mode control, supports the Pulse Skipping Modulation (PSM) with 80uA low quiescent current which assists the converter on achieving high efficiency at light load or standby condition.

The SCT2613 features fixed 480KHz switching frequency, which minimizes the external off chip passive components size and reduces the output ripple. The SCT2613 allows power conversion from high input voltage to low output voltage with a minimum 80ns on-time of high-side MOSFET and also supports low dropout operation with a low voltage difference from input to output.

The device offers fixed 6ms soft start to prevent inrush current during the startup of output voltage ramping, and compensation circuits are implemented internally which allows the device to be used with minimized external components.

The SCT2613 provides cycle-by-cycle current limit, thermal shutdown protection, output over-voltage protection and input voltage under-voltage protection. The device is available in an TSOT23-6L package.

APPLICATIONS
- 12-V, 24-V, 48-V Industry and Telecom Power System
- Industrial Automation and Motor Control
- Vehicle Accessories
- Portable Handheld Instruments
- Portable Media Players

**OPERATION**

**Overview**

The SCT2613 is a 4.5V-60V input, 1A output, buck converter with integrated 500mΩ Rdson high-side power MOSFET. It implements constant frequency peak current mode control to regulate output voltage, providing excellent line and load transient response.

The SCT2613 features fixed 480KHz switching frequency, which minimizes the external off chip passive components size and reduces the output ripple. The SCT2613 features an internal 6ms soft-start time to avoid large inrush current and output voltage overshoot during startup. The device also supports monolithic startup with pre-biased output condition. The seamless mode-transition between PWM mode and PSM mode operations ensure high efficiency over wide load current range. The quiescent current is typically 80uA under no load or sleep mode condition to achieve high efficiency at light load.

The SCT2613 has a default input start-up voltage of 4.23V with 200mV hysteresis. The EN pin is a high-voltage pin with a precision threshold that can be used to adjust the input voltage lockout thresholds with two external resistors to meet accurate higher UVLO system requirements. Floating EN pin enables the device with the internal pull-up current to the pin. Connecting EN pin to VIN directly starts up the device automatically.

The SCT2613 full protection features include the input under-voltage lockout, the output over-voltage protection, over current protection with cycle-by-cycle current limiting, output hard short protection and thermal shutdown protection.

**Peak Current Mode Control**

The SCT2613 employs fixed frequency peak current mode control. An internal clock initiates turning on the integrated high-side power MOSFET Q1 in each cycle, then inductor current rises linearly. When the current through high-side MOSFET reaches the threshold level set by the COMP voltage of the internal error amplifier, the integrated high-side MOSFET is turned off.

The error amplifier serves the COMP node by comparing the voltage of the FB pin with an internal 0.765V reference voltage. When the load current increases, a reduction in the feedback voltage relative to the reference raises COMP voltage till the average inductor current matches the increased load current. This feedback loop well regulates the output voltage to the reference. The device also integrates an internal slope compensation circuitry to prevent sub-harmonic oscillation when duty cycle is greater than 50% for a fixed frequency peak current mode control.

The SCT2613 operates in Pulse Skipping Mode (PSM) with light load current to improve efficiency. When the load current decreases, an increment in the feedback voltage leads COMP voltage drop. When COMP falls to a low clamp threshold (470mV typically), device enters PSM. The output voltage decays due to output capacitor discharging during skipping period. Once FB voltage drops lower than the reference voltage, and the COMP voltage rises above low clamp threshold. Then high-side power MOSFET turns on in next clock pulse. After several switching cycles with typical 160mA peak inductor current, COMP voltage drops and is clamped again and pulse skipping mode repeats if the output continues light loaded.

This control scheme helps achieving higher efficiency by skipping cycles to reduce switching power loss and gate drive charging loss. The controller consumption quiescent current is 80uA during skipping period with no switching to improve efficiency further.

**Enable and Under Voltage Lockout Threshold**

The SCT2613 is enabled when the VIN pin voltage rises above 4.23V and the EN pin voltage exceeds the enable threshold of 1.223V. The device is disabled when the VIN pin voltage falls below 4.03V or when the EN pin voltage is below 1.13V. An internal 1uA pull up current source to EN pin allows the device enable when EN pin floats.

EN pin is a high voltage pin that can be connected to VIN directly to start up the device.

For a higher system UVLO threshold, connect an external resistor divider (R1 and R2) shown in Figure 9 from VIN to EN. The UVLO rising and falling threshold can be calculated by Equation 1 and Equation 2 respectively.
\[ R3 = \frac{V_{\text{rise}} \times 0.924 - V_{\text{fall}}}{3.076uA} \]  

\[ R4 = \frac{R3 \times 1.13}{V_{\text{fall}} - 1.13 + R3 \times 4uA} \]

where

- \( V_{\text{rise}} \) is rising threshold of Vin UVLO
- \( V_{\text{fall}} \) is falling threshold of Vin UVLO

**Output Voltage**

The SCT2613 regulates the internal reference voltage at 0.765V with ±2.5% tolerance over the operating temperature and voltage range. The output voltage is set by a resistor divider from the output node to the FB pin. It is recommended to use 1% tolerance or better resistors. Use Equation 3 to calculate resistance of resistor dividers. To improve efficiency at light loads, larger value resistors are recommended. However, if the values are too high, the regulator will be more susceptible to noise affecting output voltage accuracy.

\[ R_{FB,\text{TOP}} = \frac{V_{\text{OUT}}}{V_{\text{REF}}} \times R_{FB,\text{BOT}} \]  

where

- \( R_{FB,\text{TOP}} \) is the resistor connecting the output to the FB pin.
- \( R_{FB,\text{BOT}} \) is the resistor connecting the FB pin to the ground.

**Internal Soft-Start**

The SCT2613 integrates an internal soft-start circuit that ramps the reference voltage from zero volts to 0.765V reference voltage in 6ms. If the EN pin is pulled below 1.13V, switching stops and the internal soft-start resets. The soft-start also resets during shutdown due to thermal overloading.

**Bootstrap Voltage Regulator and Low Drop-out Operation**

An external bootstrap capacitor between BOOT pin and SW pin powers the floating gate driver to high-side power MOSFET. The bootstrap capacitor voltage is charged from an integrated voltage regulator when high-side power MOSFET is off and the external low-side diode conducts. The recommended value of the BOOT capacitor is 0.1 \( \mu \text{F} \).

The UVLO of high-side MOSFET gate driver has rising threshold of 2.45V and hysteresis of 250mV. When the device operates with high duty cycle or extremely light load, bootstrap capacitor may be not recharged in considerable long time. The voltage at bootstrap capacitor is insufficient to drive high-side MOSFET fully on. When the voltage across bootstrap capacitor drops below 2.2V, BOOT UVLO occurs. The converter forces turning on an integrated low-side MOSFET periodically to refresh the voltage of bootstrap capacitor to guarantee the converter's operation over a wide duty range.

During the condition of ultra-low voltage difference from the input to the output, SCT2613 operates in Low Drop-Out LDO mode. High-side MOSFET remains turning on as long as the BOOT pin to SW pin voltage is higher than BOOT UVLO threshold 2.45V. When the voltage from BOOT to SW drops below 2.2V, the high-side MOSFET turns off and low-side MOSFET turns on to recharge bootstrap capacitor periodically in the following several switching cycles. Low-side MOSFET only turns on for 100ns in each refresh cycle to minimize the output voltage ripple. Low-side MOSFET may turn on for several times till the bootstrap voltage is charged to higher than 2.45V for high-side MOSFET working normally. The effective duty cycle of the converter during LDO operation can be approaching to 100%.
During slowing power up and power down application, the output voltage can closely track the input voltage ramping down thanks to LDO operation mode. As the input voltage is reduced to near the output voltage, i.e. during slowing power-up and power-down application, the off-time of the high side MOSFET starts to approach the minimum value. Without LDO operation mode, beyond this point the switching may become erratic and/or the output voltage will fall out of regulation. To avoid this problem, the SCT2613 LDO mode automatically reduces the switching frequency to increase the effective duty cycle and maintain regulation.

**Over Current Limit**

The SCT2613 implements over current protection with fold back current limit. The SCT2613 cycle-by-cycle limits high-side MOSFET peak current to avoid inductor current running away during unexpected overload or output hard short condition.

When overload or hard short happens, the converter cannot provide output current to satisfy loading requirement. The inductor current is clamped at over current limitation. Thus, the output voltage drops below regulated voltage with FB voltage less than internal reference voltage continuously.

The SCT2613 implements frequency fold back to protect the converter in unexpected overload or output hard short condition at higher switching frequencies and input voltages. The oscillator frequency is divided by 1, 2, 4, and 8 as the FB pin voltage falls from 0.765 V to 0 V. The SCT2613 uses a digital frequency fold back to enable synchronization to an external clock during normal start-up and fault conditions. During short-circuit events, the inductor current can exceed the peak current limit because of the high input voltage and the minimum on-time. When the output voltage is forced low by the shorted load, the inductor current decreases slowly during the switch off-time. The frequency fold back effectively increases the off-time by increasing the period of the switching cycle providing more time for the inductor current to ramp down.

With a maximum frequency fold back ratio of 8, there is a maximum frequency at which the inductor current can be controlled by frequency fold back protection. Equation 4 calculates the maximum switching frequency at which the inductor current remains under control when $V_{OUT}$ is forced to $V_{OUT \_SHORT}$. The selected operating frequency must not exceed the calculated value.

\[
f_{sw(max \_sk(p))} = \frac{f_{DIV}}{t_{min \_ON}} \times \frac{I_{LIMIT} \times R_{DC} + V_{OUT \_SHORT} + V_d}{V_{IN \_MAX} - I_{LIMIT} \times R_{DS(on)} + V_d}
\]

where

- $I_{LIMIT}$: Limited average current
- $R_{DC}$: Inductor DC resistance
- $V_{IN \_MAX}$: Maximum input voltage
- $V_{OUT \_SHORT}$: Output voltage during short
- $V_d$: Diode voltage drop
- $R_{DS(on)}$: Integrated high side FET on resistance
- $T_{min \_ON}$: Controllable minimum on time
- $f_{DIV}$: Frequency divide equals (1,2,4 or 8)

**Over voltage Protection**

The SCT2613 implements the Over-voltage Protection OVP circuitry to minimize output voltage overshoot during load transient, recovering from output fault condition or light load transient. The overvoltage comparator in OVP circuit compares the FB pin voltage to the internal reference voltage. When FB voltage exceeds 110% of internal 0.765V reference voltage, the high-side MOSFET turns off to avoid output voltage continue to increase. When the FB pin voltage falls below 105% of the 0.765V reference voltage, the high-side MOSFET can turn on again.
SCT2613

Thermal Shutdown

The SCT2613 protects the device from the damage during excessive heat and power dissipation conditions. Once the junction temperature exceeds 173°C, the internal thermal sensor stops power MOSFETs switching. When the junction temperature falls below 163°C, the device restarts with internal soft start phase.

</tbody>
</table>
Output Voltage

The output voltage is set by an external resistor divider R1 and R2 in typical application schematic. Recommended R6 resistance is 10.2KΩ. Use equation 5 to calculate R1.

\[ R_1 = \left( \frac{V_{OUT}}{V_{REF}} - 1 \right) \times R_2 \]  

(5)

where:

- \( V_{REF} \) is the feedback reference voltage, typical 0.765V

Under Voltage Lock-Out

An external voltage divider network of R3 from the input to EN pin and R4 from EN pin to the ground can set the input voltage’s Under Voltage Lock-Out (UVLO) threshold. The UVLO has two thresholds, one for power up when the input voltage is rising and the other for power down or brown outs when the input voltage is falling. For the example design, the supply should turn on and start switching once the input voltage increases above 8V (start or enable). After the regulator starts switching, it should continue to do so until the input voltage falls below 7V (stop or disable). Use Equation 6 and Equation 7 to calculate the values 127 kΩ and 22.1 kΩ of R3 and R4 resistors.

\[ R_3 = \frac{V_{rise} \times 0.924 - V_{fall}}{3.076uA} \]  

(6)

\[ R_4 = \frac{R_3 \times 1.13}{V_{fall} - 1.13 + R_3 \times 4uA} \]  

(7)

Inductor Selection

There are several factors should be considered in selecting inductor such as inductance, saturation current, the RMS current and DC resistance(DCR). Larger inductance results in less inductor current ripple and therefore leads to lower output voltage ripple. However, the larger value inductor always corresponds to a bigger physical size, higher series resistance, and lower saturation current. A good rule for determining the inductance to use is to allow the inductor peak-to-peak ripple current to be approximately 20%~40% of the maximum output current.

The peak-to-peak ripple current in the inductor \( I_{LPP} \) can be calculated as in Equation 8.

\[ I_{LPP} = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times L \times f_{SW}} \]  

(8)

Where

- \( I_{LPP} \) is the inductor peak-to-peak current
- L is the inductance of inductor
- \( f_{SW} \) is the switching frequency
- \( V_{OUT} \) is the output voltage
- \( V_{IN} \) is the input voltage

Since the inductor-current ripple increases with the input voltage, so the maximum input voltage in application is always used to calculate the minimum inductance required. Use Equation 9 to calculate the inductance value.

</table>
\[ L_{\text{MIN}} = \frac{V_{\text{OUT}}}{f_{\text{SW}} \cdot L_{\text{IR}} \cdot I_{\text{OUT(max)}}} \times (1 - \frac{V_{\text{OUT}}}{V_{\text{IN(max)}}}) \]  

Where

- \( L_{\text{MIN}} \) is the minimum inductance required
- \( f_{\text{SW}} \) is the switching frequency
- \( V_{\text{OUT}} \) is the output voltage
- \( V_{\text{IN(max)}} \) is the maximum input voltage
- \( I_{\text{OUT(max)}} \) is the maximum DC load current
- \( L_{\text{IR}} \) is coefficient of \( I_{\text{LP}} \) to \( I_{\text{OUT}} \)

The total current flowing through the inductor is the inductor ripple current plus the output current. When selecting an inductor, choose its rated current especially the saturation current larger than its peak operation current and RMS current also not be exceeded. Therefore, the peak switching current of inductor, \( I_{\text{LPEAK}} \) and \( I_{\text{LRMS}} \) can be calculated as in equation 10 and equation 11.

\[ I_{\text{LPEAK}} = I_{\text{OUT}} + \frac{I_{\text{LP}}}{2} \]  
\[ I_{\text{LRMS}} = \sqrt{\left(I_{\text{OUT}}\right)^2 + \frac{1}{12} \left(I_{\text{LP}}\right)^2} \]

Where

- \( I_{\text{LPEAK}} \) is the inductor peak current
- \( I_{\text{OUT}} \) is the DC load current
- \( I_{\text{LP}} \) is the inductor peak-to-peak current
- \( I_{\text{LRMS}} \) is the inductor RMS current

In overloading or load transient conditions, the inductor peak current can increase up to the switch current limit of the device which is typically 1.6A. The most conservative approach is to choose an inductor with a saturation current rating greater than 1.6A. Because of the maximum \( I_{\text{LPEAK}} \) limited by device, the maximum output current that the SCT2613 can deliver also depends on the inductor current ripple. Thus, the maximum desired output current also affects the selection of inductance. The smaller inductor results in larger inductor current ripple leading to a lower maximum output current.

**Diode Selection**

The SCT2613 requires an external catch diode between the SW pin and GND. The selected diode must have a reverse voltage rating equal to or greater than \( V_{\text{IN(max)}} \). The peak current rating of the diode must be greater than the maximum inductor current. Schottky diodes are typically a good choice for the catch diode due to their low forward voltage. The lower the forward voltage of the diode, the higher the efficiency of the regulator.

Typically, diodes with higher voltage and current ratings have higher forward voltages. A diode with a minimum of 60-V reverse voltage is preferred to allow input voltage transients up to the rated voltage of the SCT2613.

For the example design, the B360A-13-F Schottky diode is selected for its lower forward voltage and good thermal characteristics compared to smaller devices. The typical forward voltage of the B360A-13-F is 0.7 volts at 3 A.

The diode must also be selected with an appropriate power rating. The diode conducts the output current during the off-time of the internal power switch. The off-time of the internal switch is a function of the maximum input voltage, the output voltage, and the switching frequency. The output current during the off-time is multiplied by the forward voltage of the diode to calculate the instantaneous conduction losses of the diode. At higher switching frequencies, the ac losses of the diode need to be taken into account. The ac losses of the diode are due to the charging and discharging of the junction capacitance and reverse recovery charge. Equation 12 is used to calculate the total power dissipation, including conduction losses and ac losses of the diode.
The B360A-13-F diode has a junction capacitance of 200 pF. Using Equation 12, the total loss in the diode at the maximum input voltage is 0.39 W.

If the power supply spends a significant amount of time at light load currents or in sleep mode, consider using a diode which has a low leakage current and slightly higher forward voltage drop.

$$ P_D = \frac{(V_{IN,MAX} - V_{OUT}) \times I_{OUT} \times V_d}{V_{IN,MAX}} + \frac{C_j \times f_{SW} \times (V_{IN} + V_d)^2}{2} $$  \hspace{1cm} (12)

**Input Capacitor Selection**

The input current to the step-down DCDC converter is discontinuous, therefore it requires a capacitor to supply the AC current to the step-down DCDC converter while maintaining the DC input voltage. Use capacitors with low ESR for better performance. Ceramic capacitors with X5R or X7R dielectrics are usually suggested because of their low ESR and small temperature coefficients, and it is strongly recommended to use another lower value capacitor (e.g. 0.1μF) with small package size (0603) to filter high frequency switching noise. Place the small size capacitor as close to VIN and GND pins as possible.

The voltage rating of the input capacitor must be greater than the maximum input voltage. And the capacitor must also have a ripple current rating greater than the maximum input current ripple. The RMS current in the input capacitor can be calculated using Equation 13.

$$ I_{CINRMS} = I_{OUT} \times \sqrt{\frac{V_{OUT}}{V_{IN}} \times (1 - \frac{V_{OUT}}{V_{IN}})} $$ \hspace{1cm} (13)

The worst case condition occurs at $V_{IN}=2\times V_{OUT}$, where:

$$ I_{CINRMS} = 0.5 \times I_{OUT} $$  \hspace{1cm} (14)

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

When selecting ceramic capacitors, it needs to consider the effective value of a capacitor decreasing as the DC bias voltage across a capacitor increasing.

The input capacitance value determines the input ripple voltage of the regulator. The input voltage ripple can be calculated using Equation 15 and the maximum input voltage ripple occurs at 50% duty cycle.

$$ \Delta V_{IN} = \frac{I_{OUT}}{f_{SW} \times C_{IN}} \times \frac{V_{OUT}}{V_{IN}} \times (1 - \frac{V_{OUT}}{V_{IN}}) $$ \hspace{1cm} (15)

For this example, three 4.7μF, X7R ceramic capacitors rated for 100 V in parallel are used. And a 0.1 μF for high-frequency filtering capacitor is placed as close as possible to the device pins.

**Bootstrap Capacitor Selection**

A 0.1μF ceramic capacitor must be connected between BOOT pin and SW pin for proper operation. A ceramic capacitor with X5R or better grade dielectric is recommended. The capacitor should have a 10V or higher voltage rating.

**Output Capacitor Selection**

The selection of output capacitor will affect output voltage ripple in steady state and load transient performance.

The output ripple is essentially composed of two parts. One is caused by the inductor current ripple going through the Equivalent Series Resistance ESR of the output capacitors and the other is caused by the inductor current ripple charging and discharging the output capacitors. To achieve small output voltage ripple, choose a low-ESR output
capacitor like ceramic capacitor. For ceramic capacitors, the capacitance dominates the output ripple. For simplification, the output voltage ripple can be estimated by Equation 16 desired.

$$\Delta V_{OUT} = \frac{V_{OUT} \cdot (V_{IN} - V_{OUT})}{8 \cdot f_{SW}^2 \cdot L \cdot C_{OUT} \cdot V_{IN}}$$

(16)

Where

- $\Delta V_{OUT}$ is the output voltage ripple
- $f_{SW}$ is the switching frequency
- $L$ is the inductance of inductor
- $C_{OUT}$ is the output capacitance
- $V_{OUT}$ is the output voltage
- $V_{IN}$ is the input voltage

Due to capacitor's degrading under DC bias, the bias voltage can significantly reduce capacitance. Ceramic capacitors can lose most of their capacitance at rated voltage. Therefore, leave margin on the voltage rating to ensure adequate effective capacitance. Typically, one 22μF ceramic output capacitors work for most applications.

Layout Guideline

The regulator could suffer from instability and noise problems without carefully layout of PCB. Radiation of high-frequency noise induces EMI, so proper layout of the high-frequency switching path is essential.

1. Minimize the length and area of all traces connected to the SW pin, and always use a ground plane under the switching regulator to minimize coupling.
2. The input capacitor needs to be very close to the VIN pin and GND pin to reduce the input supply ripple. Place a low ESR ceramic capacitor as close to VIN pin and the ground as possible to reduce parasitic effect.
3. Output inductor should be placed close to the SW pin. The area of the PCB conductor minimized to prevent excessive capacitive coupling.
4. UVLO adjust and RT resistors, loop compensation and feedback components should connect to small signal ground which must return to the GND pin without any interleaving with power ground.
5. Route BOOT capacitor trace on the other layer than top layer to provide wide path for topside ground.
6. The layout needs be done with well consideration of the thermal. A large top layer ground plate using multiple thermal vias is used to improve the thermal dissipation. The bottom layer is a large ground plane connected to the top layer ground by vias.

Figure 23. PCB Layout Example
Thermal Considerations

The maximum IC junction temperature should be restricted to 125°C under normal operating conditions. Calculate the maximum allowable dissipation, \( P_{D\text{(max)}} \), and keep the actual power dissipation less than or equal to \( P_{D\text{(max)}} \). The maximum-power-dissipation limit is determined using Equation 14.

\[
P_{D\text{(MAX)}} = \frac{125 - T_A}{R_{\text{JA}}}
\]  

(14)

where

- \( T_A \) is the maximum ambient temperature for the application.
- \( R_{\text{JA}} \) is the junction-to-ambient thermal resistance given in the Thermal Information table.

The real junction-to-ambient thermal resistance \( R_{\text{JA}} \) of the package greatly depends on the PCB type, layout, thermal pad connection and environmental factor. Using thick PCB copper and soldering the GND to a large ground plate enhance the thermal performance. Using more vias connects the ground plate on the top layer and bottom layer around the IC without solder mask also enhance the thermal capability.
NOTE:

1. Drawing proposed to be made a JEDEC package outline MO-220 variation.
2. Drawing not to scale.
3. All linear dimensions are in millimeters.
4. Thermal pad shall be soldered on the board.
5. Dimensions of exposed pad on bottom of package do not include mold flash.
6. Contact PCB board fabrication for minimum solder mask web tolerances between the pins.
